Normative relativism, another version of ethical relativism, is about principles and not cultural differences. In essence, normative relativism will put forward a principle stating that what is good for one individual or society is not considered like that for another individual or society. This principle can be considered just like another version of descriptive relativism, but it does not stop there. The principle will continue to state that what is “really” good in one case will not be in another (Frankena 1973, p. 109). Normative relativism

makes it difficult to talk about universal moral systems, and it may end up claiming that there is no possibility to ever know the absolute truth.

Third relativist position talks about the justification of moral judgments so it can be called meta-ethical relativism. This position will claim that there is no rational justification possible to consider one ethical judgment better than the other. Although all this may be the case, differences in opinions on ethics should not be taken as a reason to hold every ethical position as having the same value.

An example of relativism in ethics is the classic utilitarian approach where the justification for action is found in the consequences of that action. In other words, utilitarianism will focus on the goals of a proposed action, and actions should be judged right if their consequences are good, i.e., if they increase the amount of good in the world.

Definition

Ethical banking is a fairly broad term that refers to the bank's business integration with sustainable development goals or social, environmental, and ethical (SEE) criteria. In other words, ethical banking aims to encompass a sustainable and ethical banking system involving eco- and social-friendly practices. Both internal and external driving forces may motivate conventional banks to transform into ethical banks. Internal driving forces may rise from shareholders, board of directors, and employees. External driving forces may come from the general public, governments, local societies, nonprofit-making governmental organizations (NGOs), customers, and competitors. Although there are no clear definition and regulatory rules that distinguish ethical banks from conventional banks, ethical banks voluntarily follow some ethical beliefs/principles in their finance and investment projects. Ethical banks may also be stimulated to develop more sustainable products, for instance, green funds or environmental, social, or ethical investment funds. Ethical banks value their universal existence by providing transparent corporate information and positive social and environmental impacts to the public. In general, ethical banks seek to promote fair-trade opportunities and provide social enterprise supports and ethical consumerism while making financial and lending decisions. The term "ethical" can be used interchangeably with social banking, green banking, or sustainable banking. For example, banks can claim themselves as ethical banks by supporting local green initiative projects. According to the definition of Schultz (2010) in the Green Bank report, green banking involves banks' engagement in eco-friendly conscious practices. It aims to reduce carbon footprint from their banking activities, such as online banking or paperless banking applications.

Business Objectives

Business ethics will become irrelevant if banks choose profit maximization as the primary

business objective. One way to enhance the operation of banks' business is to incorporate social, environmental, and ethical (SEE) issues by building up corporate social responsibility (CSR) guidelines within the traditional banking business model (San-José et al. 2011). However, this is not precisely to be all-inclusive ethical commitments when making financial decisions. According to San-José et al. (2011), ethical bank owners can decide the company's rules and objectives on the aspects of SEE issues. The business acts by following its moral beliefs, standards, and regulation to determine its essential value. The decision from the owners related with ethical issues is a big challenge.

Various synonyms have been used in practice with the concept of ethical banking, such as Triodos banking, Islamic banking, green banking, sustainable banking, and environmental or social banking. All of them have an ethically related business objective. For example, Triodos Bank, established in the Netherlands in 1980, is a specialist ethical savings bank. The aim is to invest in businesses that seek to address social and environmental issues, such as solar energy, healthcare, and charities. In addition, savers can make an agreement on their investments to finance a particular industry or project; business loans are limited to the organizations which are involved in sustainable development projects. It is well known that a firm's corporate governance performance and its social, environmental impacts have become the leading performance indicator in the industry. According to the Association of British Insurers' (ABI) study in 2008, firms with good corporate governance produced 18% higher returns than firms with poor corporate governance; shareholders suffer from low returns by investing in a poorly governed firm (Selvaggi and Upton 2008). San-José et al. (2011) identify that transparency of information, placement of assets, guarantees, and participation make ethical banking different from other traditional banks (such as saving banks, commercial banks). The objective of ethical banking seeks both economic and social benefits, which can fit into a socioeconomic model.

The Environmental Issues

Due to the emphasis on environmental issues, banks initially concentrate on the "direct" or "internal" issues related to banks' business processes, such as electricity, water, and paper usage issues. The potential energy saving of banks is enormous, as can be seen from the achievements of these proactive companies. For example, Dutch banks agreed with the Dutch government to cut their energy by 25% from a 1996 baseline by 2006 and achieved a successful result (Jeucken and Bouma 1999). UBS and NatWest Group achieved similar result. Some of the financial services firms also use renewable energy to improve their internal environmental performance. For example, the Rabobank Group uses solar energy. The Co-operative Bank in the UK introduced the first biodegradable credit card in 1997, in support of Greenpeace (Jeucken 2001). Generally speaking, banks' energy-saving actions are cost-effective, not because of legislative pressure. Credit Suisse has developed an instrument to measure its environmental impacts, which summarized that energy usage is by far its most profound impact, accounting for 90% of all cumulative pollution within the organization (Jeucken 2001). UBS used a similar approach named "Environmental Performance Evaluation." Other environmental reports from banks also conclude that energy is one of the most significant aspects. The measurement of environmental performance and comparison of that performance between banks, however, remains challenging.

Furthermore, banks have been disinclined to promote environmental focus from the external side. Banks recognize these as "external" issues or "indirect" issues associated with the products of banks provided. The banks' products themselves do not pollute the air, water, and land and even do not produce hazardous chemicals. Instead, it is the users who can have an impact on the environment. The funds' channel through the banks' lending schemes may indirectly cause environmental damages. Banks, therefore, need to have an incentive to understand the environmental implications when making lending decisions, primarily how the loans will be used in practice. As

debated by many scholars, banks' lending activities could be associated with potential threats to the natural environment (Sarokin and Schulkin 1991; Thompson 1998). Thompson and Cowton (2004) also argued that a bank's lending portfolio impacts the natural environment. Overall, how banks perceive and deal with its social and environmental responsibility associated with their lending activities is still under debate in recent decades.

Future Directions

It is very objective to determine what is ethical and claim to be an ethical bank. It is impossible to have a universal definition that distinguishes ethical banks from conventional banks. Ethical banks are regulated similarly to traditional banks and must abide by the same regulatory rules. Although many ethical banks voluntarily become ethical, certain levels of supervisory and regulatory ethical policies or ethical codes of conduct are needed to set up the rules. According to Cowton and Thompson (2000), banks who signed the United Nations Environment Programme (UNEP) statement did not act significantly different from the non-signatories. Hence, an external regulatory body or monitor body needs to be in place to set minimum acceptable legal standards. Certain degrees of enforcement methods should be in place to make ethical codes to be more effective.

Ethical conflict; Ethical problems; Moral conflict;
Moral dilemmas; Moral problems

Definition

Ethical dilemmas refer to those situations in which the individual has to choose between two alternatives that are both considered unacceptable from a moral point of view. The decision maker is in a conflictual state of mind and needs to analyze the problem more thoroughly in order to make the best decision in those circumstances. In most cases, the individual will have to make a compromise. One of the strongest dilemmas in the literature is known as *Sophie's choice* after the novel with the same name

written by William Styron in 1979 or the trolley dilemma. When facing with an ethical dilemma, the decider has the following choices: one of the opposing alternatives or not choosing anything at all. In order to make the best or the right decision in a specific situation, the individual should address the right questions and formulate as clear as possible the ethical dilemma and the alternatives, as well as the consequences for each decision (alternative 1, alternative 2, or no alternative). For clarifying these issues, a person should communicate the problem to a person he/she trusts or a specialist in ethical problems that could help him/her with the decision. The concept of ethical dilemmas should be an important part of ethical trainings conducted in organizations, thus helping the employees in the decision-making process and contributing to a higher level of morality within the company. People are confronted with these types of dilemmas both in their personal and professional lives, so an important role is played by education (formal and nonformal) and lifelong learning.

Introduction

According to Cambridge Dictionary ([n.d.](#)), a dilemma refers to a “situation in which a difficult choice has to be made between two different things” someone could do. So, an ethical or a moral dilemma is a particular type of dilemma that involves moral principles and norms. If someone has to choose between eating an apple or an orange, this could be seen as a dilemma but not as an ethical dilemma. When faced with an ethical dilemma, the decision maker takes into account his or her own moral principles and values. There is no correct answer to an ethical dilemma, which is also dependent on the cultural context of the decider. Some decisions could be seen as moral in some countries and in others as immoral. Fernando (2009) defines ethical dilemmas in business as a situation in which the decision maker has to choose between two alternatives that impact both the stakeholders and also the profitability and competitiveness of the company.

The main characteristics of an ethical dilemma are – it presents two alternatives; it reflects a conflictual state; the alternatives are both unacceptable from a moral perspective; the alternatives are analyzed through the lens of moral principles; and it requires an in-depth analysis of all aspects involved. There are different types of ethical dilemmas, starting from the simplest ones to the ones that are very complicated and extreme, involving the lives of other people around us (*Sophie's choice* when a mother has to choose which of her children will be killed and the *trolley dilemma* when someone has to choose between one or five individuals to die). There is no precise solution for ethical dilemmas, but the literature presents a few strategies that can help individuals better address these conflictual situations and prepare them for the choices they will have to make.

Types of Ethical Dilemmas

Hanson (2014) appreciates that there are six main ethical dilemmas with which any professional in any field is dealing with: a worthwhile work in which the individual creates an equilibrium between the market needs, and someone's skills and values; work versus family dilemma, the individual having to choose between these two facets of his/her life; going with the crowd despite of his/her own beliefs; following misleading leaders or staying loyal to his/her moral values; being a positive change agent in the organization even if no one is doing anything; and using someone's skills for the career or for the common good of community.

Another classification of ethical dilemmas is made by McConnell (2014) but in a more abstract way: epistemic versus ontological dilemmas (in epistemic dilemmas, the decider knows which is the correct decision; meanwhile in ontological dilemmas, the decider has difficulty in choosing one of the two alternatives because of their similarity in terms of morality); self-imposed (an internal conflict) versus those imposed by the society (someone from the outside making pressures on the subject to choose

between two alternatives); and obligation dilemmas (the decider has the obligation to choose at least a feasible alternative) versus prohibition dilemmas (all feasible alternatives are forbidden).

Kidder (2009) presents four common ethical dilemmas closer to those presented by Hanson. These are: truth versus loyalty (personal honesty or loyalty to others); individual interest versus community interest; short term versus long term (decisions in the present affect the future); and justice versus mercy for the individuals affected.

Weiss (2008, p. 98) presents ethical dilemmas from the perspective of the levels where they might arise: "the individual level, the organizational level, the industry level and the societal, international and global level." Collins (2017) classifies ethical dilemmas in conscious and unconscious; in conscious dilemmas, the decision maker knows which decision is bad and which is wrong but is still inclined to choose the wrong one for the benefits brought afterward; meanwhile in unconscious dilemmas, the decision maker is not aware of the moral connotation of his or her decision.

According to Dignum (2019), the decisions that follow the ethical dilemmas are different because people have different perspectives, are coming from various cultures, and have different religions and different political views. Ethical dilemmas are linked to the cultural background of a person because his/her moral values dictate the solution to a dilemma, and many of these answers are influenced by someone's culture (Pettifor and Ferrero 2012; Muller and Desmond 1992; Pitta et al. 1999). As Pitta, Fung, and Isberg (1999, p. 242) put it, "a country's culture is directly related to the ethical behavior of its managers." Thus, there are different perspectives on ethical issues and dilemmas in accordance with someone's culture and also different laws. Graafland, Kaptein, and Mazereeuw-van der Duijn Schouten (2006, p. 53) analyze the relationship between ethical dilemmas and religion, stating that "the frequency with which dilemmas arise is directly related to various aspects of religious belief."

Strategies for Solving Ethical Dilemmas

The process of solving an ethical dilemma is similar with the process of decision-making; it involves a decision maker, a few alternatives, and a strategy used in order to increase the chances of making the best decision in some specific circumstances. Sometimes, there is no right decision, but a decision should be made to reduce the casualties, such as in Sophie's choice or the trolley dilemma.

There are numerous opinions and views regarding this issue in the professional literature, most of them being adjusted to the field the ethical dilemmas appear (healthcare, business, administration, etc.). McGoff (2017) mentions the following three strategies: reconcile the ethical dilemmas using "and" instead of "versus" (short and long term, the individual and the community, truth and loyalty, and justice and mercy); have the outcome in mind; and insure the commitment of the group affected by the decision. Kidder (2009, p. 23) developed the three principles that could help individuals make better decision when facing ethical dilemmas: end-based (refers to the utilitarianism and implies doing the greatest good for the greatest number), rule-based (the decision is made according to a standard such as in Kantianism), and care-based (choose what you would want others to choose if you were impacted by the others' decision).

Sweetwood (2016) presents a six-step method to solve an ethical dilemma: never lie; take your time to think; take into account the legalities involved; consult with experts in the field; choose a strategy based on logic and facts; and have confidence in your decision and communicate it to the others. Forester-Miller and Davis (2016) created a seven-step model for ethical decision-making: identifying the problem, applying the Code of Ethics, determining the dimension of the dilemma, establishing the potential solutions for solving the dilemma, taking into account the consequences for each solution and choosing the best one, and evaluating the chosen solution and implementing it. This process is similar with any other process for decision-making.

Other strategies for choosing the best alternative when facing an ethical dilemma might involve answering questions such as: Is it legal? Is it in accordance with your code of honor/will you sleep well doing that? If it will be made public, how would you feel about it? And what would your close friends and family think of your decision and of you doing that? Coughlan and Connolly (2008) take into account two main elements that the employees consider when solving their ethical dilemmas: justification and emotions. The same link between emotions and ethical dilemmas is presented by Linehan and O'Brien (2017) who highlight the importance of expectations from other people to the way individuals make ethical choices.

Jennings (2014) proposes six steps for solving ethical dilemmas in business: have knowledge on all the available facts about a situation; establish the information that is needed and is not available for the moment; analyze the impact of a potential decision regarding the ethical dilemma on all stakeholders; list all alternatives for solving the dilemma; evaluate the alternatives taking into account all consequences and costs; and choose a recommendation for resolving the ethical dilemma.

According to Saleem (2006, p. 276), there are ethical tools that can be used by the management of an organization in order to help employees better handle ethical dilemmas. Thus, the author mentions ethics committees which train the employees on issues regarding ethics at the workplace and also having ethics officers inside the organization or from outside the company that have expertise in dealing with this type of problems. Other ethics tools that can be used are ethics codes, having a dedicated phone line for whistleblowers, and having procedures and policies. All these create an ethical background that encourages employees to express their concerns on ethical matters in the organization and try to find out solutions for solving the ethical dilemmas they have.

No matter what strategy the individuals use, there is no perfect solution for an ethical dilemma. Some are more complex than others, requiring a

thorough analysis, and some others have to be solved instantly, the individual not having the possibility to wait if he/she wants to make a decision (Sophie's choice or trolley dilemma is a dilemma that has to be solved rapidly). If an ethical dilemma does not pass the legality test (meaning that one of the alternatives is not legal), the choice is simple, but otherwise, things get more complicated. In other circumstances, all alternatives seem bad, but not choosing anything would be worse.

Ethical Dilemmas in Business

According to Ferrell, Fraedrich, and Ferrell (2009, p. 63), ethical dilemmas in business refer to one of the following issues "abusive or intimidating behaviour, lying, conflicts of interest, bribery, corporate intelligence, discrimination, sexual harassment, environmental issues, fraud, insider trading, intellectual property rights, and privacy issues." Kibert et al. (2012) mention that the *development of technology* also brings ethical dilemmas related to individuals' privacy, data security, or some consequences that can interfere with people's rights or the environment we live in.

Arrington (2017) presents the *paradox of consumerism* and highlights the idea that consumption choices can bring ethical dilemmas for consumers of fashion items. Thus, the author argues that there is a paradox in this ethical dilemma of these consumers, because they say they decide what garments they buy taking into account ethics, but their decisions reveal the opposite. Culiberg and Bajde (2014) also address the implication of consumers who participate in the tax evasion process not requiring a receipt or accepting to not receive one. Other works related to ethical consumerism and the ethical dilemmas among consumers are presented by Lingnau, Fuchs, and Beham (2019) in a study about sustainable coffee production, by Longo, Shankar, and Nuttall (2019) who highlight the connection between ethical dilemmas and the knowledge on a sustainable life. Moraes et al. (2017) present the ethical dilemma in consumption of luxurious jewelries and offer the example of diamond rings; in

their example, the ethical dilemma refers to buying or not buying a ring if the exact origin of the diamond is not exactly known in order to be sure that is not a cover for unethical business.

Knox (2020, p. 449) refers to the *ethical dilemmas in corporate social responsibility* stating that companies are dealing with the decision to implement socially responsible programs for the community or be socially responsible to the stakeholders. For the author, ethical dilemmas mean a conflict between two "ethical imperatives" that in this specific example are both honorable.

Another type of ethical dilemma in business is mentioned by Zhang et al. (2019) who refer to the *dilemma in financial reporting* as a consequence of product harm crisis. The authors mention that some managers facing this problem choose to save the situation on a short run despite the unfortunate consequences on the long run in order to present a financial report that does not look so bad in the stakeholders' eyes.

Clarke and Boersma (2017) consider the complexity of a *global supply chain* and the multitude of ethical dilemmas that arise related to employment and environment and present the example of Asian plants that produce components for Apple. Even if this is one of the most powerful companies in the world, financially speaking and also in terms of brand value, the company did not succeed to solve these ethical dilemmas in its value chain.

Monnot et al. (2019) bring attention to the ethical dilemma of *overpackaging* in retailing, companies having the option to choose less packaging and protect the environment or to overpackaging and ensure that the consumers' intentions will not change because of the lack of visual stimulation.

Ciulli, Kolk, and Boe-Lillegraven (2019) mention the ethical dilemma related to food waste and recovery. At first glance, it would seem that it is ethical for retailers to donate the food close to its expiration date, but as the authors highlight, some managers fear their reputation will suffer and they will be perceived as not being efficient in organizing their business. As a solution, the authors present the concept of the digital platforms which connect the business that wants to reduce food waste with potential recipients.

Summary

Ethical dilemmas refer to two conflicting alternatives or potential behaviors that are not satisfying or acceptable from a moral perspective. As the professional literature shows, there are different types of ethical dilemmas with different complexity and strongly dependent on the cultural and religious beliefs of an individual. There are different strategies that can help individuals in making ethical choices and solve their dilemmas following the same pattern as in the case of a decision-making process. Ethical tools such as ethical codes, ethical committees, ethical trainings, ethical audits, and ethical phone lines that ensure anonymity and procedures and policies inside the organization can all be beneficial in the process of helping employees to resolve their ethical dilemmas. These can appear at individual level, at a society level, or at an organizational level. Related to consumers' ethical dilemmas, it might be helpful to increase the awareness on ethical issues at the level of a society and introduce ethics courses in formal education. Progress has brought with it a wider range of ethical dilemmas that should be addressed carefully.

[Behavior theories](#); [Bioethics theories](#); [Moral principles](#); [Morals theories](#)

Definition

Ethical theories are that set of philosophical-juridical theories that try to define a human behavior deontologically defining it right, legitimate or wrong, and illicit. A particular aspect of ethics is the bioethics or ethics of life.

Introduction

Trying to find what is philosophically and legally right and what is wrong is the task of the scholars of ethical theories. In parallel with the growth of scientific experimentation, the need to define some human activities deontologically has also grown. In the past, these answers were provided especially by the religion that also regulated the activities of the followers culturally (Marini 2012). Today the interference of scientific research and the experimentation of techniques that open up unexplored future scenarios are interposed on a line that is difficult to define and

requires important insights by scholars of these disciplines. We talk about these scenarios in the field of bioethics.

Bioethics contains in its studies animal tests, analysis, and experimentation activities on embryos and the human genome, on the use of stem cells in the treatment of rare and incurable diseases in our present, of genetically modified organisms (GMOs), and of their inclusion within the animal and human food trade, the development of nanotechnologies.

These ethical issues are also associated with those relating to the environment and the conservation of natural ecosystems and victims of the great climatic upheavals caused by human activities.

ἦθος – Behavior

The word ethics derives from the Greek word “ἦθος – behavior” which in its widest form gathers the human, political, juridical, and moral aspects. But in its narrowest sense, it describes the philosophical aspect of the search for a right or wrong “behavior,” of good or evil. In ancient Greece from Homer to Hesiod, from Socrates to Aristotle, philosophers wondered what good was, what behavior led to “virtue.” Aristotle, who introduced the term “ethics,” saw good as an essential nature of man. Happiness is the ultimate goal and is reached with a life according to reason.

All societies, religions, and groups have their principles and rules of conduct. These principles led to the construction of ethical theories. Society is a system that organizes individuals to allow their lives through standards recognized by all its members. If law and morality are called upon to apply these standards, bioethics deals with problems relating to the emergence of new phenomena. If the law and morals judge phenomena, bioethics, the ethics of life, study them to assess the risks and benefits of it, possibly including changing the standards themselves. With the advancement of science and research, the boundary of ethics has considerably shifted.

Bioethics tries to take a holistic approach by studying complex entities in their entirety by

examining interactions between multiple elements rather than the individual elements in a separate manner (Stoeklé et al. 2019). Especially in the last few decades, the bioethical debate has focused on very current issues that have seen the involvement of communities in addition to political participation, which is also religious. Among these issues considered relevant, we find animal tests, xenotransplantation, genome engineering, assisted fertilization and euthanasia, stem cells, and experiments on embryos, GMOs, and nanotechnologies.

Animal tests are part of the new problems that the citizens of many countries are paying great attention to. After the atrocities of Nazism in the Germany of the Second World War and after the Nuremberg trial, the prohibition of experiments on human beings was established. The Helsinki Declaration and the National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research (1974) and the resulting Belmont Report set the goal of creating protection about research on human beings by drawing up principles of respect, charity, and justice.

For this reason, subsequent experiments have been conducted with animal tests, to which it was decided to also support a high risk of death to obtain scientifically significant results. During the last century, however, the question was raised about the ethics of animal experiments, raised by a social conscience that is increasingly attentive to the idea that human or animal life should always be protected. It has also been shown that animals fully experience exposure to the experiment and suffer a lot (Ferdowsian and Beck 2011).

Thus, in the near future, animal experiments will give way to experiments conducted with the use of new technologies. Analysis technologies, computer models, and cell cultures in vitro will increasingly help to achieve this important goal. Computers, new software, and specialized computer models that can be used and created soon will increasingly help develop an understanding of biology. Thanks to their use, the practice of vivisection can cease and space will be given to a new limit on the use of guinea pigs.

The problem of *xenotransplantation* is always linked to the theme of animals. This type of

practice involves the transplantation of cells, tissues, or organs from one animal to another of different species.

We often hear of *genome engineering*, that is, the practice that involves the insertion of human genes into the animal gene to produce cells, tissues, or organs that the human body does not reject, an immunological barrier to be investigated on which many studies took place, considering it foreign to itself (Platt and Bach 1991). Xenotransplantation will become important for clinical emergencies and in the absence of donors of human organs, but the ethical debate remains open whether or not it is the right practice to carry out.

Cloning has raised the ethical debate for its possible application to the human race. Genetic engineering has placed the study of the human genome at the center of this topic. DNA manipulation has seen bioethics scholars oppose the possibility of changing characteristics of the human being through scientific practices (eugenics). Within this research, we include studies on human embryos. Such studies that would include trials are prohibited in many countries. The ethical debate on the use of *stem cells* concerns the possibility of extracting undifferentiated cells of three types: totipotent, capable of transforming into any part of organic tissue; pluripotent, they transform into many tissues but not all; and unipotent, only cells of a type. Embryonic stem cells are at the center of the ethical debate although it is forbidden in many countries to find such cells from embryos that are not intended for assisted reproduction.

Assisted fertilization and *euthanasia* are two other hot topics for those who debate about ethics. The first is a much-debated topic since it does not only concern couples who need assistance to have a child but is part of a very articulated debate that sees heterologous fertilization as a topic of discussion that is carried out with a partner third to the couple, cloning, surrogacy, and sometimes trade and experimentation on embryos for research purposes. The second is a particularly delicate issue because not only does it provide an ethical analysis on the possibility of privately choosing to die but, as we speak of “assisted

suicide,” it also involves the involvement of third parties and therefore non-negligible legal aspects. Relevant in the development of a reflection on the subject of euthanasia is the condition of the applicant, who often, in the countries where this practice is allowed, is ill with very serious and incurable diseases as well as degenerative diseases. The patient who, due to the illness, experiences a constant malaise and pain asks to die to put an end to his suffering. Euthanasia involves two types of actions: a “commissive,” which requires that a person materially practices euthanasia on the patient, and the other “omissive,” that is, let the patient die without applying any type of therapy to him. In both cases, the ethical-moral-legal problem is not easy to solve and is dealt with differently from country to country (Barcaro 1998).

As mentioned in the area of bioethics investigation, the problem related to *genetically modified organisms* or *GMOs* is also included. These organisms undergo a modification of part of the genome through genetic engineering techniques to manipulate a given characteristic. Since the beginning of the laboratory experiment, the scientific community and the political world have magnified these bodies to carefully evaluate both their potential and their risks. To date, the debate on the marketing of genetically modified organisms is very heated among countries that have decided to include them, albeit in small quantities, and others that still today prefer not to market them. Although there is no scientific evidence of GMO risk cases, consumers, especially in the European Union, are very reluctant to see them marketed in their market. The European Union itself applies very stringent assessments on the potential risk related to the use of GMOs for food purposes. Their presence must also be reported precisely and clearly on the product label.

Still in Europe, one wonders if GMOs can cause environmental damage. Seven factors are evaluated:

the persistence and invasive potential of the genetically modified plant; the transfer of genes from the plant to microorganisms; the interactions of the genetically modified plant with the target

organisms; the interactions of the genetically modified plant with nontarget organisms; the impact of cultural practices; the effects on biogeochemical processes; and the effects on human and animal health (Arpaia and Paoletti 2015).

Various types of damage to the environment are therefore feared. It is feared that pollen may be dispersed or that DNA is spread directly into the soil through the roots, which can lead to an involuntary spread of the gene inserted in the genetically modified plants and transfer their characteristics to other individuals; it is feared that the genes expressed may directly or indirectly damage other organisms leading to a significantly negative impact on biodiversity; it is feared that organisms harmful to plants adapt to the genes expressed by genetically modified plants, becoming more difficult to control even in “traditional” crops. All these concerns require an accurate analysis, a careful evaluation of the scientific data already in possession, and a calculation of the probabilities that a risk factor can materialize.

The development of increasingly sophisticated technologies has led to the emergence of large technologies in the order of nanometers: *nanotechnologies*. Nanotechnology operates in a multidisciplinary field moving from mechanical and chemical engineering to molecular biology and bioengineering. These new and sophisticated technologies, besides having a practical application in IT, have an important application in medicine and at a pharmacological level (drug delivery). We also study possible applications such as “utility fog,” objects that change shape, within robotics projects or as weapons for military purposes.

The debate on the development and use of nanotechnology has not failed to develop especially for this last aspect with the concern that more and more deadly weapons of mass can be built that is difficult to counteract. A research carried out by the University of Wisconsin, which aimed to question public opinion on these technologies, reveals that the opening to enlargement and their use was more opposed by those who had a certain religious affiliation and a certain cultural belonging. Obviously the more the issues invest in

the daily life of the citizens, the more an ethical and moral problem is raised about what is good and what is not.

Environmental ethics, instead, is born from the awareness of the human being of the surrounding nature: of plants, animals, and ecosystems in their entirety and complexity. What passed in the 1970s of the last century is the attention to the study of the natural environment and the true increase in interest in the subject (Rolston 2003). And yet the ethics of the environment is not easy to apply if we think that in today's world, it would mean implementing all those actions that put the current development model into question.

If we want to pay attention to the ethics of the environment, it would quickly lead to contrasting global warming, limiting demographic growth, questioning the current consumption and distribution of wealth, as well as demanding greater inclusion of women and indigenous conditions.

This is because nature and human life have always intertwined destinies and a cure for the former means taking care of the latter. Men must include nature in their concept of ethics that too often took into consideration the relationships between them but not the relationships with nature, leading to not taking care of them and destroying the delicate ecosystems. Just think of extinct species due to man, destroyed forests, global warming, intensive fishing, resource exploitation, land use, and air and water pollution.

Climate change and the relative extreme weather events that bring entire populations to their knees are the most dramatic demonstration of neglect in the management of the balance between man and nature, especially in the last two centuries. Man has not paid attention to resources and has not paid attention to the thousands of species with which he shares his home.

Yet since the 1970s, various approaches to environmental ethics have been born: humanistic ethics; animal welfare ethics; biocentrism, deep ecology, and land ethics; theological environmental ethics which have developed the ethics of eco-justice; community ethics with worrying circles; the ethics of environmental virtues; axiological environmental ethics; political ecology;

the ethics of sustainable development, bioregionalism, and ecofeminism; postmodern environmental ethics; and local ethics.

Probably the error was to empty nature of its intrinsic value, justifying its exploitation with the achievement of a higher value. Human ethics have not considered the importance of natural spontaneous lives but have only thought of well-being for the benefit of human preferences. Environmental ethics takes into account all the life forms of the planet and reassigns to them an intrinsic value that it is up to the human being to protect.

Key Issues

The difficulty today is to be able to establish the ethical limits in bioethics in respect to all the communities interconnected by globalization, considering the different religious beliefs and the multiethnic cultural sensitivities while at the same time covering the road of the future at the same speed with which research and science make discoveries.

At the same time, environmental ethics clashes with the reality of a development model that has caused ongoing climate change.

Future Directions

The scientific discoveries of the last century have been unprecedented and have led to a better life of human being on our planet. The technology and the development of research, especially in the genetic field, have further increased the knowledge available in the medical field.

Globalization has meant that such knowledge was spread rapidly throughout the world as never before had been possible before this century.

The future of bioethics is to always study the benefits and risks of scientific research and to draw attention to those human studies that could often lead to unknown and unprecedented paths without knowing the results.

The future of environmental ethics will instead be that of recreating harmony between man and

nature, within a sustainable development that is the fulcrum of human activities.

Definition

Ethics (often used synonymously with moral philosophy) goes back to the ancient Greek *ethos* (ἦθος; habit, custom, as well as ἦθος; which can be translated as character and manner of mind) (Werner 2021). It can be described as a philosophical discipline that tries to answer the questions of *how should mankind live*, what is *good* and what is *bad* or what is *right* and what is *wrong* (Gewirth 1960). Derived from this, ethics tries to answer the question of which values, beliefs, and motivations underlie people to act in a certain way and what goals are being pursued (Singer 2021). Ethics attempts to answer those questions on an abstract, philosophical level as well as to address everyday human behavior and to establish codes and guidelines for action in sometimes challenging situations (Deigh 2010). Philosophers have been trying to find those answers for millennia, until today without a final, all-encompassing definition. The philosophical debate has rather illustrated the social, political, technical, and religious conditions of the epochs as well as the personal perspectives and beliefs of the philosophers and practitioners, which finally resulted in a variety of approaches and the differentiation of the term.

Introduction

The question of ethics and morality has preoccupied people since thousands of years. The first traditions date already back about 5000 years and originate from Mesopotamian societies.

Later evidence can be found in Egypt and Hebrew communities as well as the famous Greek philosophers, from whom the most detailed discussions of these issues have been handed down (Larue 2000). Perspectives and approaches have changed due to spatial and temporal circumstances and led to different debates and differentiations. Aristotle and Plato, for example, tried to answer the question of what is *good* and what is *bad* in terms of behavior that is virtuous and pursues the goal of a happy life and a clear conscience (Buchanan and Powell 2015). Younger philosophers like Thomas Hobbes, who had a very negative view of human beings, believed that moral behavior only took place on the basis of reason and fear and David Hume on the contrary argues that there are no higher universal ethical principles, but that moral behavior is driven by emotion (Gewirth 1960). With the famous *categorical imperative*, Immanuel Kant tried to find a universal answer on the question of ethical behavior, as well as a practically feasible concept of ethics and moral. Until today his definition is one of the best known and probably most controversially discussed guidelines of ethical action (Johnson and Cureton 2022). Critics accuse Kant's statement as very close to, or even a paraphrase of the *golden rule* which has existed in similar forms in various cultures since thousands of years. Further critics of Kant's maxim argue that supporters of a discriminatory political system, for example, would be perfectly compliant with Kant's principle, but at the same time absolutely unethical in their actions (Werner 2021).

More recent philosophers who have been concerned with the definition of ethics and moral action such as Richard M. Hare came to the conclusion that a universally applicable moral judgment would need to consider all people affected and target their maximum possible satisfaction (Gewirth 1960). Hare was immediately criticized by John L. Mackie who stated that a universal moral judgment needs to consider individual desires and feelings which makes Hare's perspective impossible (Vinten 2015). Unlike ancient examinations, which were often focused on the question for a happy life, today's philosophers pay

greater attention to the issue of justice. Examples are provided by Peter Unger (1996) or Thomas Pogge (2002) for whom ethical behavior is strongly linked to responsibility, solidarity, human rights, and global inequality. Another development which is becoming increasingly important is the practical application of ethics. Applied ethics tries to translate the historical debate into an applicable set of norms for various areas of human activity such as business ethics, medical ethics, etc.

This brief historical review illustrates the scope of the debate on ethics and the challenge to develop a universal definition that embraces different perspectives, opinions as well as temporal and spatial circumstances. This complexity is well illustrated and simultaneously extended by technical innovations such as the world-wide-web or global challenges, for example climate change or the coronavirus outbreak.

The following sub-disciplines help to encompass the entirety of the term ethics (Werner 2021).

1. *Meta Ethics* – is mainly dealing with the origin and meaning of ethical behavior and principles. The main objective is not to explain or justify them, but rather to explore or criticize behavioral norms or attitudes and moral judgments.
2. *Descriptive Ethics* – is mainly dealing with the description of behavior, norms of behavior, and behavior-related attitudes and value judgments.
3. *Normative Ethics* – is mainly dealing with the evaluation, content, and criteria for behavior, behavioral norms, and behavior-related attitudes and moral judgments, either for general norms or specific practical examples.

Applied Ethics – can be assigned to the category of *Normative Ethics*. *Applied Ethics* describes the systematic application of ethical norms and principles of moral behavior in different fields of human activity to provide a framework or a moral map to confront sometimes difficult issues (Singer n.d.). The following examples illustrate this differentiation and practical application.

Business Ethics

Business ethics describes the transfer of ethical principles into business relations and activities such as employee management, protection of environment, and corporate social responsibility etc. On a corporate level it includes the synergy of a company's core values such as honesty, trust, respect and fairness into its policies, practices, and decision-making. It furthermore aims to provide guidelines of what is right or wrong governance and behavior in a business environment. However, due to cultural influences, ethics in organizations varies by society, person, and the condition in which actions are taken. The successful application therefore requires their acceptance by all members as a guiding framework for interaction (Donaldson and Walsh 2015; Ferrell et al. 2019).

Environmental Ethics

Environmental issues and the increasing destruction of nature in most parts of our planet raise various ethical questions, including the ancient issue of the intrinsic value of nature and whether we are obliged to preserve nature for our descendants or if we as humans are responsible for survival of whole species of animals which many are under serious threat or already extinct due to our enormous expansion and extreme consumption of resources. Environmental ethics tries to answer those and other questions and confront perspectives like those of supporters of our growth-driven capitalist symptoms who would probably ask their calculators for the answer (Brennan and Norva 2021).

Animal Ethics Britannica Online

Animal ethics deals with the question, if humans have the right to use animals for their benefit. Historically and in people's minds there still exists the assumption that the status of nonhuman animals is by nature inferior to that of humans.

Derived from such a position it is completely obvious to use animals for entertainment, medicine, fashion, scientific advancement, pets, and food as it has been for years. Since at least the 1970 and the famous publication of *Animals, Men and Morals: An Inquiry into the Maltreatment of Non-humans* by Stanley Godlovitch et al. this perspective is increasingly questioned. Supporters of animal rights are convinced that humans have the moral duty to recognize animals as to have feelings such as fear or joy and therefore deserve to live as they wish (Singer n.d.)

Application for Ethical Correct Acting

A final example which demonstrates the actual relevance of *Applied Ethics* in recent times is the App which supports users to act ethically correct, developed by the Markkula Center for Applied Ethics at Santa Barbara University (2021). It also illustrates the evolution of the use of the term and the alienation from a philosophical discussion of moral action to an unquestioned, bite-size preparation for consumers.

Summary

The term ethics goes back to the ancient Greek word *ethos*, meaning character or manner of mind. However, the history of ethics goes back to the development of human societies. It tries to answer questions such as what is wrong, right, good, bad, or how humankind should behave. Sub-disciplines are meta-ethics, descriptive ethics, normative ethics, and applied ethics.

At its core it is concerned with human values, beliefs, and motivations that determine human actions. Ethical theories were developed by Aristotle, Plato, Thomas Hobbs, Immanuel Kant, Richard M. Hare, John L. Mackie, and others. Consequently, approaches to ethics changed and were extended over time. Today, practical application of ethics can for example be found in business ethics, animal ethics, and ethical correcting action.

Ethics and Ethical Theories

Definition/Description

Ethics is one of the philosophical disciplines concerned with understanding human behavior in the context of morality. Sometimes ethics is also called moral philosophy. Concerning method, ethics can have a descriptive method in which “that what is” is described in the context of human moral behavior and a normative method in which “that what should be” is at the center. Ethics as a philosophical discipline has various goals, but they can be listed as follows: understanding human action in the moral context and providing guidelines on human morally right action. Ethics meets its goals in several ways: (1) by providing a description of human action, (2) by helping to understand the essence of human action in regard to moral qualities, (3) by providing guidance for decision-making in

order to act in a morally correct way, and (4) by providing insight in what is considered to be specifically humane way of acting. In the course of history, three most influential normative ethical theories are virtue ethics, duty ethics, and consequentialist ethical theories.

Introduction

Human beings are forced to make decisions in their lives; even abstaining from making a decision is a decision. In most situations, there are already guidelines, experience, rules, role models, or habits which can help in making a decision, but every once in a while, there is no apparent help provided from any of the sources on what to do and what is the right decision. In such cases, ethics should help people make better decisions or at least minimize the risk of making poor decisions.

Ethics in one part, surpasses purely academic discussion on morality and moral judgments because moral decisions are part of everyday human life and they are also reflected in common questions such as “What should I do?” On the other hand, the philosophical discipline of ethics is a science about morals, and it deals with human action and character. Morals are a collection of basic rules and ways of acting which specific society deems as appropriate and proper. Ethics is also sometimes called moral philosophy. It is important to emphasize that the results of this kind of research do not stop purely on the academic level but are expected to be disseminated to everyday situations. Due to all this, ethics is a practical philosophical discipline.

Generally saying two approaches can be used when discussing morality. One approach is so-called normative ethics which tries to describe human action from a moral perspective. The second approach is normative ethics where criteria for moral decision-making are being offered and where universal moral systems are being developed.

Freedom as a Necessary Condition for Moral Responsibility

One of the presupposing conditions that have to be in place in order to discuss the morality of one's actions is that the agent acting is free. Freedom in this sense can be understood in two different ways: internal and external freedom. Internal freedom means that people are capable of rational thought and are aware of their actions. In other words, they are not internally obstructed in deciding their action, e.g., due to illness, addiction, or similar. On the other hand, external freedom means that people are not forced to act or that their actions and decisions are not obstructed in any external way. Examples of external obstruction might be being physically restrained or threatened. If the condition of freedom is not fulfilled, people should not be held morally responsible for their actions.

Descriptive Ethics

Descriptive ethics describes the behavior of human beings, their beliefs, and their values. Also, this kind of approach tries to find answers to questions such as: What is the source of morals? What is the nature and status of moral statements? Can morality be rationally established? In short, descriptive ethics deals mostly with what things “are.” In this approach, the state of things and specific facts about morality are mostly in focus. Prescribing moral rules or telling others what kind of persons they are should usually be avoided. A particular subpart of descriptive ethics is called metaethics. As part of metaethics, the true nature of morals is sought by analyzing the contents of moral statements. Generally saying, descriptive ethics is an essential way of describing and thus improving understanding of moral situations, rules, and solutions.

The primary difference between normative and descriptive ethics is that normative ethics does not deal with what things are. Instead, it tries to prescribe “what should be.” The goal of normative

ethics is establishing a universal system of morality. That means that (1) it is acceptable for all people (or even for all rational beings) and (2) is objective. For systems which have these two characteristics, it is also possible to have enough authority to compel people to follow them.

Normative Ethics

Three great traditions or theories in normative ethics are virtue ethics, duty ethics, and consequentialist ethics. What is similar to all three is that they start from the idea that it is possible to establish morality rationally. This approach is called cognitivism, and the attitude is that it is possible to know the truth about the “real” system of morality and to give universally acceptable reasons for it. All three theories have the same goal and that is to establish a universal system of morality.

Virtue (Aretaic) Ethics

The oldest ethical theory posits human excellence or virtue at its center. Ancient Greek philosophers such as Socrates, Plato, and Aristotle belonged to this tradition. Generally saying, it is with the ancient Greek philosophers that ethics as a philosophical discipline started. Socrates is considered to be a founder of philosophical ethics, while Aristotle is the first one who made it into a system, created the terminology, and called it “ethics.”

The main line of questioning that virtue ethics is concerned answering is questions related to virtues. For example: What kind of a human should I be? What kind of human do I wish to be? What kind of a human being should I be in order to fulfill the need I have as a human? It might be said that, as a part of this tradition, it is more fundamental to “be good” and then to “do good.” Emphasis is on the agent performing the act, and not so much on the act itself. In the virtue ethics framework, human character supersedes human actions. Because of that, the basic question is not “What should I do?.” Instead, the basic

question is “What would a good man do in a situation like this?” Knowing what someone good would do helps and directs the behavior of others. Being virtuous means being good. Ethicists working in this tradition created a list of virtues that people should have. For example, Aristotle emphasized wisdom, courage, temperance, and prudence. These lists do not have to end at four virtues. List-making activities can get out of hand. For example, some philosophers counted as many as 100 virtues that a person should have.

Every ethical theory has its positive and negative aspects. A downside to virtue ethics is found in mentioned lists of virtues that supposedly every human being ought to have. Such a list in a hierarchical fashion still does not exist. It seems that in order to create such a hierarchical list of virtues, there should be one principle which would determine the place of every virtue on that list. If such a principle wants to be implemented, it has to be borrowed from some other ethical tradition. So, if the situation calls for judgment between two or more virtues which can be manifested, it is not easy to know which one should come first, which one after that, and so on. Another negative side to virtue ethics is that it does not give a list of actions which are not allowed at all or are bad in themselves (e.g., murder or treason). So technically, if a good person commits treason, that act is not bad in itself. Such thinking goes against common moral intuition. On the other hand, on the positive side, it seems that this ethical tradition takes into account the complete human being and strives to provide answers to questions such as who we are and who should we be. At the same time, it keeps in mind the quality of human beings, our needs, wants, and the meaning of life and at the same time emphasizing virtues, education, and practice.

Duty (Deontological) Theory

Deontological theory points out that we are obligated to do certain things no matter what. For example, like Immanuel Kant, one of the representatives of this theory would say, we always have to treat another human being as a goal and

not as a means to an end. The most important thing is that this theory supposes that some actions are wrong in themselves, and we should not act like that. On the other hand, some actions are right, and we are obligated to do them no matter what.

While virtue theory searches for the list of virtues which are necessary to have in order to be a “good person,” deontological ethics emphasizes duty as the main criteria for making moral decisions. Probably the most influential theory in this tradition was created by a German philosopher, Immanuel Kant. Kant’s theory is best described through the categorical imperative. Kant’s categorical imperative, in one of its formulations, states the following: “act only by that maxim through which you can at the same time will that it becomes a universal law.” Let us imagine a situation in which two ethical rules state something exactly opposite as the right thing to do. The first rule states: It is morally right to speak the truth. The second rule states: It is morally right to lie. What would happen if the second rule is made universal, and not the first one? First, let us look at what makes lying possible. Lying, as an act, is possible only if a minority of people does it. If everybody told lies all the time, it would be impossible to believe anything anyone said. Lying would be made practically impossible because everybody would expect a lie. If an ethical rule “it is morally right to lie” is lifted to the status of a universal law, the consequences would be that the act of lying would be impossible. If so, then lying is not morally permissible.

Negative sides of deontological theories are that they are often too formalistic, and there is a possibility for conflict of duties. One example could be to keep a promise to a co-worker (keeping promises is a duty) even if that means that someone might lose a job because of our actions (not harming others is also a duty). It is possible that sometimes we cannot resolve the conflict among two or more duties or that sometimes actions, which we are obligated to do, have negative consequences. On the upside, duty ethics gives a strict list of allowed and prohibited duties which are more or less aligned with our everyday

moral intuitions. Besides, it also frequently provides answers to doubts when we are in no position to foresee the consequences of our actions. Last, it allows us to overcome human weakness by putting forward duties which have to be upheld no matter what other factors outside of our control might be involved.

Consequentialist (Teleological) Theory

In the consequentialist ethical tradition, there is only one criterion for deciding if something is right or wrong action. That deciding element is the consequence(s) purpose of that action. In said tradition, the action is right if its consequences are good. For consequences to be good, it usually means that they increase the amount of good in the world. The most influential theory in this tradition is utilitarianism where “good” is being understood as “utility” which in turn equals “happiness.” Two most well-known proponents of such a theory are Jeremy Bentham and John Stuart Mill.

Common to all utilitarian theories is the so-called principle of utility formulated by Jeremy Bentham. The principle states: “By the principle of utility is meant that principle which approves or disapproves of every action whatsoever, according to the tendency it appears to have to augment or diminish the happiness of the party whose interest is in question: or, what is the same thing in other words, to promote or to oppose that happiness.” (Bentham, 1789).

There are further divisions in this strategy depending on the content of what is perceived as good, or good for whom. For example, a wanted goal might be a physical pleasure (physical hedonism) or mental pleasure (intellectual hedonism). It can also be a pleasure for the individual (ethical egoism) or the collective (ethical universalism or utilitarianism).

The main issue put in front of such strategy is that if the ultimate criterion is a consequence of one action, this might lead to the idea that means are justified by presumed good consequence. In this sense, it might be possible that, for example,

	Virtue theory	Duty theory	Consequentialist theory
Representatives	Socrates, Plato, Aristotle	Immanuel Kant	Jeremy Bentham, John Stuart Mill
Basic question(s)	What kind of a human should I be?	What should I do?	What outcome do I want to achieve?
Notable ideas	Man's character supersedes man's actions so the basic question is not what I should do, or which moral law should I follow, but what would a good man do in a situation such as this.	We are obligated to do certain things no matter everything else.	Actions are right if their consequences are good, i.e., if they increase the amount of good in the world.
Emphasized	Agents	Acts	Goals

Ethics and Ethical Theories, Fig. 1 Overview of three great traditions of normative ethics

theft and hard work were both morally worthy if they were to lead to the same consequence. Besides this, it is often hard to predict the precise consequences of our actions. On the positive side, these theories avoid the conflict of duties or the nonexistence of a hierarchical list of duties. Having only the consequence in mind helps to make decision-making a lot easier (Fig. 1).

Definition

Ethics management is different from ethical management or ethics of management, being synonymous with management of ethics. It is a part of management that deals with providing an ethical climate in organizations, both public and private, using specific tools such as ethical codes, ethical committees, ethical hotlines, whistleblowing procedures, ethical audit, and ethical trainings. Kaptein (2012, p. 42) defines it as “the systematic and coherent development of activities” meant to fulfil the stakeholders’ expectations. The author

highlights that ethics management is about organization of ethics and could be seen both as “discipline and practice.” The practical aspect of ethics management is also mentioned by Menzel (2012, p. 13) that considers the four components of ethics management: “hiring, performance, training and auditing.” These components imply that ethics management is used only by managers, but the principles and the tools of ethics management should be known and applied by all employees in an organization. For example, having whistleblowing procedures in a company is part of ethics management, but these should be beneficial for both the employers and the employees, being meant to maintain an ethical climate inside the company and a good image and reputation in the community. Trevino and Nelson (2010, p. 208) attribute the importance of ethics management to the “media attention to scandals in American business” because there is a strong connection between ethics management and preventing wrongdoing in a company, thus avoiding the image deterioration. More and more consumers buy products and services from the companies that are perceived as having an ethical climate.

Introduction

Ethics management has specific tools used to prevent wrongdoing in an organization. The efficiency of these tools depends on the communication strategy of the company. If there is a good ethical code but this is not properly disseminated to the employees, the efficiency is affected. Ethics management has numerous benefits, creating loyalty among the employees, contributing to a better image and thus attracting consumers, and reducing the number of ethical problems in the company. As Alford and Bebensee (2010, p. 91) state, ethics management reduces “the likelihood of violations and improve the image of the firm.” According to Laasch and Conaway (2014, p. 140), “ethics management tools are managerial means by which to improve ethics performance.” It is useful to understand the role played by ethics management, the authors

highlighting the connection with a company’s performance. Menzel (2010, p. 51) appreciates that ethics management tools “range from soft” measures (e.g., “exemplary leadership”) to “more concrete measures” (e.g., ethical audits and trainings).

Ethics Management Tools

Ethical Codes/Codes of Conduct

The most known and used tool by the companies is represented by ethical codes or codes of conduct. There are different terms used for these: codes of conduct, ethical codes, ethics codes, codes of ethics, and ethics codes of conduct. According to Collins English Dictionary (www.collinsdictionary.com/dictionary/english/ethical-code), the “ethical code is a set of moral principles used to govern the conduct of a profession,” and according to Merriam-Webster dictionary (www.merriam-webster.com/dictionary/code%20of%20ethics), the code of ethics is “a set of rules about good and bad behavior.” Both definitions have in common the set or rules or moral principles, but the latter is more comprising, not being limited to a specific profession. And the reality of business ethics nowadays shows us that these codes govern all activities and behaviors in an entity, be it public or private. These codes bring numerous benefits for companies, but with a few conditions. First, these codes should be communicated to all the employees and managers in a company, otherwise even if a code is very good and complete, the advantages will not be seen in practice. Mika (2010, p. 37) highlights that codes of ethics are “ineffective and not useful for corporations” when there is a “wrong implementation” of them.

But if these codes are well disseminated, they contribute to creating a more ethical climate inside the organizations and improve its image among consumers, thus creating loyalty. The main aim of ethical codes is to prevent bad behaviors or as Gilman (2005) states, to “guide behavior,” but there should also be some punitive measures against these behaviors if they occur. These codes are for people who “want to act ethically,” because bad people are not interested in the rules

included in such codes. Slobodkin (1993, p. 337) appreciates that some codes are better than others because they “eliminate as many dilemmas as possible.” Communication is another important element of a good code of ethics.

Ethical Committees

Another important and very frequently used tool by companies is the ethics or ethical committee. This is “a formal group of individuals . . . ensuring ethical decision-making in an organization” (McDonald 2014, p. 396). So, the main aim is similar with that of ethics codes of conduct with the exception that this is a body that applies the punitive measures against wrongdoing, if there are violations of the moral rules stated in the codes.

Unfortunately, there are both public and private entities that fail with the prevention characteristic of ethics committees, these meeting only after something bad has happened. As with ethical codes that have to be communicated to all employees, ethical committees should meet on a regular basis in order to efficiently prevent bad behaviors. An ethical committee should have a structure that offers a voice to all the parties involved in the organization’s activities (employees, owners, managers, customers, shareholders, and ethics experts). According to Deloitte (2014, p. 7), the main goal of this committee is to “ensure that the company behaves like a responsible corporate citizen” and covers all areas (sustainability, the environmental and social impact, the safety of the working place, and fair relations with all stakeholders).

The main responsibilities of these ethical committees are – ensure a proper communication of the values and rules included in the ethics code, offer guidance for the employees that are facing an ethical dilemma, create a space for debates on ethical matters, discuss ethical violations, apply punitive measures against those who violated the rules in the ethical code, create the possibility for employees to use ethical hotlines safely, without retaliation against them, communicate periodically about the cases brought to its attention, and revise ethical codes if they are incomplete or outdated.

Ethical Hotlines and Whistleblowing Procedures

These tools are related in most cases, because for ensuring anonymity to whistleblowers (those employees that reveal wrongdoing in a company), there is a real need to offer a dedicated ethical hotline. But these ethical hotlines can also be used by those employees who have an ethical dilemma and do not want to reveal themselves. Ethical hotlines can be extended to other means of communication such as a dedicated e-mail or a mail-box. The main goal of this tool is to increase the ethical climate of the organization, to prevent wrongdoing, to reduce the number of ethical problems, and to protect whistleblowers from retaliation. Sometimes, for confidentiality reasons and for the employees to feel safer, these hotlines are outsourced to a company specialized in these matters. Even if the main target is represented by the employees, the companies’ business partners can also use them, thus increasing the trust between companies and ensuring a clean business environment.

Whistleblowing procedures are meant to protect whistleblowers from retaliation, and they should be included in a good ethical code. For efficiency, these procedures should be communicated to the staff, otherwise the employees will not feel safe to reveal the wrongdoing. These tools (ethical hotlines, whistleblowing procedures) should be correlated with the other tools used in ethics management in order to be efficient (ethical codes, ethical committees, and ethical trainings) and included in the company’s strategy.

Ethical/Ethics Trainings

According to Kaptein (2012, p. 166), an ethics training is meant to “improve and safeguard the ethics of an organization.” Usually, these programs are conducted by ethics experts from outside the company that help the employees to be better prepared to cope with ethical dilemmas they are facing at work. The main functions of ethics trainings are – to communicate the ethics codes of the company to the employees and have a debate on it, to analyze real case studies involving ethical issues, to have interactive meetings with the employees in order to adjust the

program to their needs, and to have Q&A sessions to explain them how to deal with their problems and how they can reveal wrongdoing without retaliation. Liao and Teng (2010, p. 16) conducted a research and they concluded that “ethics training leads to higher employee satisfaction,” so this tool of ethics management provides many benefits for the company: a more ethical climate and more satisfied and productive employees. Even if these ethics trainings are good, if the employees do not treat them seriously, they do not aim their target, so the company’s manager should make the employees understand their importance.

Ethical/Ethics Audit

This is a tool that provides a “systematic evaluation of an organization’s ethics program and performance to determine whether it is effective” (Ferrell et al. 2009, p. 233). These tools, in order to be efficient, should be regularly conducted. The ethics audit can be internal and external, both with advantages and disadvantages. The internal audit is conducted by someone inside the company, specialized in ethics, having the advantage of being very well informed of the company’s problems, but also the disadvantage of being too subjective. On the other hand, the external specialist that conducts the ethics audit is more objective but might not have the full picture on the company’s problems.

As the other tools of ethics management, ethics audits are helpful because they lead to a cleaner environment in the company, improve the company’s image, and build trust and loyalty with the customers, the partners, and the employees. The audits help the company identify the weaknesses and implement a strategy for having a more ethical climate.

Summary

Ethics management is an important area of management and should be implemented by all organizations, both public and private. Its tools (ethics codes, committees, audits, trainings, and whistleblowing procedures) have to be

communicated to all the parties involved in the company’s activities (employees, customers, and business partners) and made public (on the company’s website or social media channels and in annual reports). This communication strategy combined with ethics management will help the company to build a strong image in the community, showing that it is a socially responsible organization. An ethics code will be effective if it includes all the problems met by the staff at their workplace, an ethical training will be successful if the employees will be active and involved in Q&A sessions, and ethics hotlines will help whistleblowers to reveal the wrongdoing if they ensure anonymity. In order to be efficient, all tools should be implemented with the employees’ participation.

University of Helsinki, Helsinki, Finland

Synonyms

[Ethics in sustainability education](#)

Definition

Ethics of sustainability education (see ► [Ethics](#); ► [Sustainability Education and Environmental Awareness](#)) is not a definite concept nor does it have a clear definition. It could be understood in at least three ways. First, it could denote that *ethics* is the focus of *sustainability education*, that is, sustainability education emphasizing ethics, for example, through sustainability focused learning content, or critical ethical teaching or learning processes. Second, it could mean an *educational* view of *sustainability ethics*, or the search for educational tools to promote the ethics of sustainability. The first and second interpretations are overlapping and indistinct, and both could be either a content or a methodical choice, or both (see Dahl 2015; Valera and Preece 2020). Third, the ethics of sustainability education raises questions about the ethical concerns that appear when implanting the issue of sustainability through education, which means that the third definition is interested in the *intrinsic ethical dilemmas* related to *sustainability education*. This third view is thus primarily theoretical and reveals that sustainability can be implemented in various ways in education, dependent on the degree of normativity in the educational practice (Wolff 2011, 2020). Increasingly, the role of education in relation to sustainability is seen as a tool for transformation, but transformation as a learning process (see ► [Transformative Learning](#)) is complicated and sometimes questionable. Therefore, sustainability education needs to be discussed from an ethical view. In that discussion, all three definitions above are interconnected, even if the last is the most crucial.

Introduction

The signs of global climate change (see ► [Climate Change](#)) have become increasingly visible, and weather changes take place frequently and suddenly. This happens even in unexpected places causing tremendous disasters for people and other parts of nature (NASA 2021; Swain et al. 2020). Consequently, biodiversity (see

► **Biodiversity**) is declining, and human migration is increasing, because of extreme weather circumstances (McCoy et al. 2014). The COVID-19 pandemic has also shown that sudden dangers may turn up and change human life independent of where people live and how much they earn (UN DESA 2021). However, the extent of these jeopardies is not the same everywhere nor for all world inhabitants, and neither are the implements for handling the risks. In this situation, political measurement like footprints (see ► **Ecological Footprint**, ► **Carbon Footprint**), planetary boundaries, and payments for ecosystem services are not enough; they may even be deceptive. The measurements are not apolitical or uncontroversial (Smith 2019). Since they only count physical limitations, they easily neglect the social and cultural margins (Butler 2017; Fricker 2002; Smith 2019) or forget to see the power (see ► **Power Equalizing**) structure this counting is trapped in (Smith 2019). Butler (2017, p. 59) argues that “humanity needs to appraise its stocks and prospects, environmentally and socially; the threats civilization faces are far higher than most experts and governments acknowledge.” The climate change dilemma requests consideration of what human life is aiming for, and ethics has a central role in that debate (Gardiner 2010).

When instrumental methods fail, the underlying ethical perspectives appear. Unequal conditions especially create ethical matters (Banks 2020) but also ecological matters. Therefore, more and more voices are asking for a paradigm shift for new values and altered economic, social, and political ideologies (see, e.g., Becker 2011; Biermann 2021; Kallis 2011; Wolff 2020). The United Nation’s 2030 Agenda and the SDGs (see ► **Sustainable Development Goals (SDGs)**, ► **Sustainable development**), like many other education policy documents, request change and transformation, and they also address education (UN 2015). Researchers increasingly ask for sustainability education that is transformative and interdisciplinary, even transdisciplinary (see ► **Transdisciplinary Learning**) (Baumber 2021). Therefore, an ethical perspective on sustainability education is crucial, but the question is how and to

what extent education can contribute to the changes the alarming unsustainability situation calls for.

All since the 1970s, education has been regarded as an important tool to contest the challenges of unsustainability, but the methods are ambiguous and the theory base is vague. The empirical studies do not consider who learns about what and why – learning just seems to happen. Researchers studying sustainability transition seldom refer to learning built on in-depth learning theories (Gerlak et al. 2018; Van Mierlo et al. 2020). To propose education as a rescuer of a globe in crisis might overestimate how far or deep education can reach, at least if education remains unchanged. Even if education has an urgent role, it is questionable whether unaided it can make the world sustainable. The education systems may even reinforce unsustainability.

The definition of “ethics of sustainability education” at the beginning of this text is tripartite. Since all three ways of understanding ethics of sustainability education are intertwined, all of them will be discussed in the sections that follow. However, emphasis lies on the third description, the intrinsic ethical dilemmas (see ► **Ethical Dilemmas**) that relate to sustainability education. Ethical discussion starts with some background on how ethics could be interpreted in that context.

Ethics

Ethics, or moral philosophy, is one of the main branches of philosophy and is concerned with understanding human behavior in the context of morality and, thus, with what are morally right or wrong conduct and good or bad characters (some philosophers treat “ethics” and “morals” as distinct) (e.g., Banks 2020). Ethics has most often dealt with human relations and human welfare, but according to Banks, ethics also includes the welfare of animals and whole ecosystems. Ethical reflections include meta-, descriptive, and normative perspectives (Banks 2020). Metaethics problematizes the meaning and utilizing of moral concepts and the justification of moral judgments. Ethics deals with theories of moral values and

provides guidelines for action, whereas normative ethics considers the rules of conduct.

Examples of *ethical questions* are as follows: How should we live? What shall we aim at? Is it right to be dishonest if the aim is good? In connection with sustainability issues, ethical questions are as follows: Is it just to live a wealthy life while others are starving? Is it wrong to clone humans or to use animals in medical research? Do animals have rights? Is it right that people in countries with weaker legislation when it comes to protecting nature and securing labor rights produce food and equipment to be consumed in richer countries? Very difficult ethical questions are as follows: Which obligations does this generation have to future generations? How can people living now defend the rights of those not yet living?

Ethics is often discussed in relation to *values* (see ► [Value](#), ► [Value Creation](#)), but the two concepts, ethics and values, are not synonyms. Whereas ethics is a set of rules governing the behavior of a person, values refer to the beliefs which a person has a lasting preference for, or in other words the degree of importance of something. Value theory “concerns which things are good or bad, how good or bad they are, and, most fundamentally, what it is for a thing to be good or bad” (Hirose and Olson 2015, p. 1). Both ethics and values are central when discussing sustainability issues.

For ages, it has been tempting to create *ethical theories* as guidelines for decisions. The main ethical theories are *consequentialism*, *deontology* (duty ethics), and *virtue ethics* (see ► [Ethical Theories II](#)). These are all mainly based on Western philosophy, which turned out to be limited, overlooking other views and moral concepts (Wareham 2017). Even if the Western theories are extensive, they are not diverse enough to include moral ideas from the entire world and are not always suited to producing sustainability outlooks.

Sustainability and Ethics

Sustainability is intrinsically related to ethics, and ethics is central both to individual and at the social

level (Becker 2011; Kibert et al. 2011). Sustainability ethics covers humans’ relationships with others of their own species and their relationships with other species and to nonliving nature. In addition, sustainability ethics includes not yet living creatures and other parts of nature under circumstances that no one can even imagine.

Ethical traditions shape people’s thinking and acting and are context dependent. Therefore, other cultures and their ideas have to be heard in the sustainability debate. In addition to Western cultures, African, Asian, Eastern European, and a great number of indigenous people’s conceptions of the world also have to be acknowledged in the sustainability discourse (e.g., Callicot 2014; Wareham 2017). Several more ethical theories than the three already mentioned have emerged since the middle of the twentieth century, like deep ecology and new materialism giving non-human nature a central role. Arne Næss, who was influenced by the thoughts of Gandhi and Spinoza, was the builder of *deep ecology* or what he called *ecosophy*. Deep ecology sees humans as integrated parts of a nature and is a distinction to *shallow ecology* with a tendency to regard humans as superior to the nonhuman world. In addition, Næss (2003) emphasized comprehensible thoughts and actions and did not think about environmentalists as reliable educators if they hide what they believe in, since morality involves controlling physical and mental desires. When mastering their desires, people have reached self-knowledge and thus happiness. Gandhi (1938) calls this *Swaraj*.

Other branches of ethics are ecofeminism, stressing the connection between the domination of women and nature, environmental pragmatism with a strong practical interest (Palmer et al. 2014), and care ethics emphasizing care about other humans as well as nonhuman nature (Johns-Putra 2013). The feminist Karen Barad (e.g., 2003) has initiated a post-humanistic ontology emphasizing that humans are not externally “in” nature but active “parts” of nature like other (nonhuman) material agents. “We do not obtain knowledge by standing outside of the world; we know because ‘we’ are of the world” (Barad 2003, p. 829). In contemporary philosophy, worldviews

prioritizing individuals and their self-realization prior to collectives or nonhumans increasingly meet critique (Callicot 2014; Johns-Putra 2013). Likewise, voices stressing the neglecting of future creatures become louder.

Ethics as the Focus in Sustainability Education

In the policy document *Our Common Future*, sustainable development is defined as a development that “meets the needs of the present without compromising the ability of future generations to meet their needs” (UN NWCED 1987, p. 16). According to this definition, contemporary society members are responsible for people living now as well as of future generations. The present generations are not allowed to deprive coming generations from the necessities they might need to live a good life (Kibert et al. 2011). This calls for vast changes in thinking, policies, and economic assumptions, since many world inhabitants already lack essentials. Low-income countries face pressing problems and may be unable to afford to care for anything other than the present. Furthermore, future generations of poor countries are likely to be among those hit hardest by climate change and environmental degradation. Therefore, people in high-income countries have an obligation to care for the most vulnerable and their future. The now living humans also need to realize essential changes in their existence to prevent future humans from suffering and enable them to have a humane life and fulfill basic human needs. It is a huge challenge in terms of human rights, to ensure the future generations the same opportunities as the present generation (Bos and Düwell 2016). When opening these kinds of issues for the students to reflect on and discuss, the complexity of the entire sustainability problematics becomes visible.

In the book *Traditional Ecological Knowledge: Learning from Indigenous Practices for Environmental Sustainability*, Shilling (2018, p. 3) proposes ethical questions. They could build a good framework for ethical discussions in a sustainability education context:

Something should be sustained, but what? The planet’s non-renewable resources, South America’s economy, or a privileged country’s lifestyle? And for what purpose? To aid developing nations, grizzly bears in Montana, Indigenous peoples, or a Fortune 500 company? And underneath it all, who gets to answer those questions?

From an ethical perspective, sustainability education must encourage critical understanding and engagement in all the dimensions of sustainability, from ecological to social justice values (Dahl 2015). Ethically based sustainability education has to uncover prejudices and norms that regulate human actions. In addition, it encourages students to think independently, to question deep-rooted principles and power constellations in the social contexts they are part of, and to overthrow generally defended arguments (Wolff 2011). Sustainability education develops the students’ ability to analyze critically, discuss, find alternatives, choose and decide, and creatively go beyond previous knowledge and understanding. This acknowledges that sustainability education is more than content knowledge within the various disciplines and recognizes that its holistic and transformative nature depends on students developing a sense of agency and empowerment. Besides cognitive skills, sustainability engages emotions and embodied experiences. That is, students not only learn to understand but also to act sustainably. Students have much to bring to the learning situation themselves, sometimes more than the teachers. Sustainability calls for student-centered methods, encouraging the students to become active collaborative learners in dynamic learning environments without clear limits between teachers and learners (Jeronen et al. 2017).

An Educational View of Sustainability Ethics

From an educational view, ethics have to do with how and what to plan, teach, and learn about moral sustainability-related issues. Therefore, it includes the objectives, the learning content, the methods, and process evaluation. Understanding

the enormous challenge of human-induced climate change and its effect on human societies is a relevant and illustrative example of a complicated educational issue (e.g., Skarstein and Wolff 2020). The climate change dilemma requires both humans with deep scientific knowledge and understanding of how humans influence the climate. To understand the dilemma in all its complexity demands knowledge from many disciplines.

Yet, learning of sustainability ethics-related issues not only demands cognition but also emotions and embodied learning. Sustainability is a human challenge related to political and cultural issues initiating not only questions about the past and the presence but also very tricky questions about the future. This strongly relates to ethics.

According to Hamilton (2017), it is problematic that humans use their autonomy without responsibility. He calls for an alternative attitude to nature, which would be built on a thorough understanding of power and responsibility. He wishes to take a cognitive leap that is a shift from primarily focusing on humans and their culture to a focus on the Earth's systems and on how humans influence these systems. Hamilton wants humans to learn to reflect on the limits of the planet, instead of concentrating on fulfilling their own egoistic dreams.

Since ethics are shaped in collaboration, education focusing on ethics and values flourish in an open all-inclusive process, in which mutual viewpoints promote growth and learning (Strahovnik 2017). The sustainability issues become ethical topics and are addressed in various subjects both inside the learning institutions and in cooperation with external partners. To help the students adapt to sustainability, the learning institutions need to implement sustainability comprehensively and convincingly, which means they have to act as sustainability models at a whole institution level (Wals 2020). Sustainability needs to become a motto or ethos not only in education but also in the managing of educational institutions and in their interactions with the rest of

society (Wolff and Ehrström 2020; Zilliacus and Wolff 2021).

Intrinsic Ethical Dilemmas Related to Sustainability Education

Similar to other social fields, education is not neutral but closely entangled to myriad political and economic systems. To make a difference, education needs new foundations. At this point, the main contemporary educational questions are as follows: What is the most crucial role of education today, and what will it be in the future? How can education best prepare people for present and future challenges? Answers on these and other current educational questions need reflective ethical considerations. A profound change from valuing profit to prioritizing the future of the planet is a transformation built on ethics. In such a process, ethics also has to be the core of education. When education is the core, a new question emerges: What education is intrinsically ethical?

In educational contexts, ethics can play a role as both a method and an aim. When ethics implies a method, it activates the learners morally and encourages them toward a transformation that may even be unpredictable. However, if ethics is taught as a preset aim, sustainability becomes a norm. With sustainability as a fixed aim, the educators transmit their view of what sustainability is or ought to be and have a clear picture of what competencies the students need or which goals the students have to reach. As an alternative, the teacher gives the students an opportunity to envision the future rather than normatively guiding them in a specific direction. The students need skills to live in a future nobody knows anything about.

When education has aimed at sustainable development as a process or sustainability as an aim, its envois have repeatedly emphasized the need to change students' attitudes. However, researchers have increasingly rejected this normative quest for changed attitudes and stated that this is unethical. Instead, they want discussions on what ethics entails in a sustainability learning

context. Therefore, there has been an ongoing debate regarding the teaching of values and attitudes in sustainability education (Jickling 1991; Wolff 2011). Purposefully changing someone's behavior, not to talk about thinking, is all but an easy mission, and it is also disputable. It raises the question about what purposefully changing somebody's attitudes means and when and where such undertakings are defensible. Jickling and Spork (1998) argue that education has to strive toward people who know how to think, instead of adapting to predetermined behavior goals. The same problem occurs when education is driven by preset competence outcomes (see Lange 2018, 2019). Iverson (2016) claims that sustainability initiatives cannot focus on developing only individual-level competencies, like being aware of personal consumption, and reducing waste and energy. It also has to encourage the students to act and advocate for changes in policy and practices. This includes understanding of the root causes of unsustainability.

Some critical voices go further and progressively articulate that teaching has to become activism. This argument occurs in many sustainability and educational contexts. Sustainability relates to environmental, anti-globalization, and anti-colonial movements, as well as marginalized knowledge and feminist ideas (Muzzin and Tripp 2005). Feminist environmentalists claim that "speciesism" (biases favoring one's own species and thus giving humans greater moral rights than nonhuman animals) or discrimination against nonhuman species contributes to the planetary degradation. Unquestionably, there are many intersections between the arguments in the contemporary critical discourses. Feminists as well as anti-racists mean that inequity is the basis of both war and poverty, and both feminists and indigenous voices stress respect for the Earth (Muzzin and Tripp 2005).

An interesting example of alternative education is a small girls' school in India, in which they have experimented with a Gandhian philosophical approach as a combination of education, research, and activism. The option could be called a "whole school approach" in which the girls are trained in a

vocation, but many other aims are also apparent, especially a good character. Personal features that are encouraged are "self-sufficiency, inner discipline, upliftment of others, the social and environmental good, responsibility, kindness, compassion, tolerance and strong work ethic" (Germein and Vaishnava 2019, p. 254). These character features are fostered in an environment in which the students simultaneously learn, do and make, play, work, and take responsibility. The formative assessment focuses on the intellectual and conceptual development but also on physical, emotional, and social abilities, as well as skills, values, leadership, and teamwork. The ambition is to educate girls who have skills and a strong identity and see themselves as actors in the world. This is a trial to renew education through an ethical approach. Even if it might raise arguments and some may regard this as old-fashioned, it is context-adjusted and shows that contemporary education can and has to focus on other aims than strictly instrumental.

Podger, Mustakova-Possardt, and Reid (2010), three researchers from the USA, Australia, and Austria, present a somewhat similar approach addressing students and their learning in a higher education context. In a theoretical study, they practice a "whole person approach," in which they encourage critical consciousness (cf. Freire 1974) and consider learning, work, and identities as being interlinked: "when a person can relate their own sense of identity – from moral, to work-oriented for instance – to broad issues and responsibilities for sustainability, they manifest a will to learn" (p. 348).

Summary

Educational institutions are not free mediators in the sustainability process. Individuals and institutions are all intensely embedded in societies with values that are steadily created in diverse discursive practices. The power within these practices produces discourses setting the rules that legitimate the truth (Foucault 2006). Discourses produce knowledge that relates to a broader episteme

(structure of knowledge), which are specific for various historical periods (Foucault 2006). Every time and in every situation when policy makers, managers, researchers, or lecturers choose educational methods or goals, or details in study programs, timetables, or process of examination, their actions are parts of a complexity power network that transmits values and norms (Wolff 2011). In addition, there are always conflicting norms and interests, which make it challenging to address the sustainability aims and implement sustainability in study programs and courses. It is demanding to initiate an unpredicted transformation on both individual and collective levels, if both educational policy and practice are driven by normative goals aiming in incompatible directions. An important aim of sustainability education is to make all these aims perceptible. In the end, all knowledge is value-loaded and ethics-based (Jickling 2005).

One can ask what the future prospects of education are. Unsustainability is a result of colonialism and an extended overestimation of humans striving for growth and perfection (Wolff 2011). To stop mischievous development, to heal and rebuild a damaged planet, and to recognize all humans as equal is a demanding task, and it takes time. It will require policy making and technical innovations but, first and foremost, new perspectives of what it means to be human. The modern worldview may be obsolete, and the idea of individual liberty and capitalist economy is worn out. Humanity needs altered worldviews that recognize the role and rights of nonhuman nature and future life on Earth (Zilliacus and Wolff 2021). The ethical-political foundation of modernity has become delicate and needs to be improved to become more sensitive to diverse cultures and ecological boundaries and to recognize temporal and spatial challenges. An education without emphasis on ethics is worthless in that situation.

In conclusion, sustainability challenges require ethical considerations of many kinds. Yet, they could be divided into four ethical dimensions that are worthwhile considering when planning

sustainability education (see also Sauvé 1999; Wolff 2011):

1. The sphere of the self, in which people develop their self-relations and own identities
2. The social sphere, in which people interact with other species members (family, friends, and others) and relate to the entire social sphere of cultural, social, political, economic, vocational, religious, and other social fields
3. The sphere of one's relationship to the biophysical environment (the nonhuman world)
4. The sphere of the future that is the unknown challenges of future life on Earth

Sustainability education needs to display, interpret, and negotiate how these spheres interact and develop. Humans shape their sustainability understanding and activities through their view of themselves, of social relations, and of the entire planet now and in the future. These interacting ethical dimensions are not separate or hierarchical but steadily changing and developing. And they all stretch from the neighborhood to the entire planet and from history and hidden historical misconduct through the present toward the future.

It is the role of education to encourage the students to criticize normative assumptions and to find new perspectives striking a balance between collective and individual interests and between long-term and short-term goals. Education needs to empower the students and give them courage to deal with what is the most important educational endeavor: to ensure life on a vital planet today and in the future.

Description

Public authorities like the European Union (EU) play an essential part in helping and encouraging companies to operate their business in responsible ways. In the last two decades, the EU has realized a combination of voluntary and obligatory actions to advance corporate social responsibility (CSR). In 2011, the Commission of the EU announced its renewed CSR strategy. This renewed strategy entails general approaches to promote CSR and combines them with more detailed approaches for certain sectors and policy areas (EU Commission 2011). Three years later, in October 2014, the Commission of the EU published Directive 2014/95/EU, making the disclosure of nonfinancial and diversity information mandatory for large companies of public interest (EU Commission 2014). In March 2019, a staff working document (SWD(2019) 143) provided a progress overview on different CSR areas (especially “Responsible Business Conduct” and “Business and Human Rights”) (EU Commission 2019a).

Introduction

Companies have a significant influence on the lives of people around the world and the citizens in the EU – not just with regard to the products and services they sell, the jobs they offer, or the opportunities they generate, but also because they implement and shape working conditions, are

contributing to innovation, education, and training, address human rights issues, and influence the environment and people’s health. Since the early 1990s, the European Union has shown a keen interest in CSR. The EU Commission came up with its own CSR definition, describing CSR as the “*responsibility of enterprises for their impact on society*.” According to the EU Commission, CSR should be company-driven. However, the EU has also acknowledged that public authorities need to fulfill their supporting role and that voluntary policy measures and, where required, complementary regulations need to be developed and implemented (EU Commission 2019b).

The most important steps and publications of the EU are outlined below.

CSR Milestones Within the EU

- In 1993, the president of the European Commission at this time, Jacques Delors, called upon Europe’s business community and asked all business leaders to become more active and to work against social exclusion.
- In March 2000, the Council of Ministers made a new appeal, asking companies and their leaders to develop and adopt more sustainable approaches in their business conduct.
- In 2001, the CSR interest of the EU was highlighted by the publication of a Green Paper entitled “*Promoting a European framework for corporate social responsibility*” (download here: https://www.jussempier.org/Resources/Corporate%20Activity/Resources/greenpaper_en.pdf). Green Papers of the EU, in general, are documents published to encourage the debate on certain topics and this Green Paper aimed to start a wide-ranging discussion on how the EU could advance CSR at both the European and global level. In particular, this Green Paper launched a debate on how existing experiences could be used for future changes and intended to encourage the development of new and innovative practices. In addition, it encouraged discussions about how to bring greater transparency to CSR reporting and the possibilities of increasing the credibility and

reliability of CSR reporting through evaluation and validation. This EU publication suggested an approach based on the extending of partnerships and networks which would enable all actors to exchange ideas and actively participate (EU Commission 2001).

- In 2002, the Commission of the EU published the first Communication regarding CSR, entitled *“A business contribution to sustainable development”* (download here: <https://eur-lex.europa.eu/LexUriServ/LexUriServ.do?uri=COM:2002:0347:FIN:en:PDF>). This Communication included the first widely accepted European definition of CSR: *“CSR is a concept whereby companies integrate social and environmental concerns in their business operations and in their interaction with stakeholders on a voluntary basis”* (EU Commission 2002) and a European action framework for CSR. Furthermore, it proposed setting up an EU Multi-Stakeholder Forum on CSR. The goal was to promote transparency and convergence of CSR practices and instruments. The Communication also outlined that the EU Commission is committed to further promoting the incorporation of CSR principles into EU policies (EU Commission 2002).
- In 2006, the second Communication of the EU concerning CSR was published. The title was *“Implementing the Partnership for Growth and Jobs: Making Europe a pole of excellence on Corporate Social Responsibility”* (download here: <https://eur-lex.europa.eu/LexUriServ/LexUriServ.do?uri=COM:2006:0136:FIN:en:PDF>). This Communication focused on growth and jobs. It highlighted the implementation of CSR within relevant European policies and several established CSR entities, especially the “European Alliance for CSR” and the “European Multi-Stakeholder Forum on CSR.” Furthermore, it outlined the support for CSR research (EU Commission 2006).
- In October 2011, the EU Commission published a further Communication on CSR (download here: http://ec.europa.eu/enterprise/policies/sustainable-business/files/csr/new-csr/act_en.pdf). It built on the previous Communications (2002, 2006, see above) and set several milestones for public CSR policies in Europe and beyond (EU Commission 2011). Already the title “renewed EU strategy for CSR” made clear that the EU has a clear policy strategy for CSR. In this Communication, the Commission introduced a new understanding of CSR. The EU no longer refers to CSR as voluntary action beyond compliance but rather outlines that every company causes impacts which it is responsible for (EU Commission 2011). In doing so, the EU communication stresses that CSR is in the interest of both companies and the society as a whole and therefore follows the idea of “shared value,” a business concept made popular by Kramer and Porter (2011) (Martinuzzi 2012).
- In October 2014, the EU Commission published Directive 2014/95/EU, which deals with the disclosure of nonfinancial and diversity information, often referred to as CSR reporting. This Directive sets the rules for the disclosure of CSR information for large companies. By now, large companies in the EU are mandated to disclose certain information on how they conduct their business and how they manage social and environmental challenges. According to the EU, this Directive helps consumers, investors, policymakers, and other stakeholders to assess the CSR performance of large companies. At the same time, it encourages these companies to develop and implement a responsible approach to business (EU Commission 2014).
- In March 2019, the EU Commission issued a staff working document (SWD(2019) 143). This document provided an overview of the progress made regarding the implementation of corporate social responsibility. It covers environmental, social, ethical, customer, and human rights aspects (EU Commission 2019a).

The EU is very active in promoting CSR and has a CSR strategy in place. Nevertheless, the political scope governments have concerning CSR is considerable. Therefore, actual CSR policies are

determined by the social-political history of a country as well as by government majorities.

EU Definition of CSR

In 2011, the EU published a new and by now widely accepted definition of CSR. It defines CSR as “the responsibility of enterprises for their impacts on society.” Furthermore, the Commission has outlined that in order to fulfill their social responsibility, “enterprises should have in place a process to integrate social, environmental, ethical, human rights and consumer concerns into their business operations and core strategy in close collaboration with their stakeholders” (EU Commission 2011). The goal is to maximize the creation of shared value, meaning the value for the company owners/shareholders as well as the value for all other stakeholders and the society at large. At the same time, responsible business conduct enables companies to detect, mitigate, and avoid possible adverse effects of their business activities (EU Commission 2011).

Eudaimonic Management

Xavier Landes
Stockholm School of Economics in Riga, Riga,
Latvia

Synonyms

[Flourishing](#); [Functioning](#); [Self-development](#)

Definition

Eudaimonic (or eudaemonic) management is an approach inspired by a philosophical tradition dating from Aristotle. Throughout times, eudaimonia – human flourishing – has received different interpretations, starting as an ethical conception of the good life and evolving toward a psychological theory of happiness understood as ongoing self-realization. Despite the diversity of characterizations, the concept of eudaimonia has maintained its main focus on the good or happy life defined by the realization of one's capacities, virtues, potentialities, and so forth. It has also kept its dynamic aspect: eudaimonia is not a state, but a

continuous process. One is truly happy if she engages in activities that feed her *daimon* (spirit). In that context, eudaimonic management consists in importing eudaimonic psychology within the firm in order to identify managerial responsibilities toward employees, particularly in terms of work environment and career development. Eudaimonic management prioritizes the self-realization of employees by helping them to achieve their potential, their inner *daimon*. Since different eudaimonic approaches have been proposed over the last three decades (e.g., self-determination theory, psychological well-being, personal expressiveness, positive psychology), eudaimonic management could take various forms. Nonetheless all forms of eudaimonia define happiness as living or functioning well in contrast with feeling good, which is characteristic of hedonic approaches.

In the *Nicomachean Ethics*, Aristotle characterizes *eudaimonia*, literally the “good (-eu), spirit (-daimon),” as the ultimate good. To be eudaimonic – or act eudaimonically – consists in being virtuous and bettering one's higher capacities (related to the mastery of reason, the upper part of the soul). The ancient conception could be read as elitist and moralist, articulating a view of where the good life depends on following thick ethical principles.

Since the antiquity, eudaimonia has evolved. Over the last decades, it has received various interpretations and experienced a revival outside philosophy, especially among happiness researchers (e.g., Edward L. Deci, Richard M. Ryan, Alan S. Waterman, Corey L. M. Keyes, Carol Ryff, Martin P. Seligman). Most of the interpretations have abandoned, or at least attenuated, the ethical dimension of the Aristotelian formulation. The core idea of the ultimate good as a continuous process of one's self-betterment remains. The moral content has, however, been watered down, and virtues are not anymore strictly defined, considered as applying to everyone or offering a blueprint of the good life.

In short, contemporary eudaimonists claim not to advance anymore a moral theory that prescribes a strict and univocal way of life. They acknowledge individuals' differences of capacities, skills,

inclinations, or, as Martin Seligman (2004) puts it, “character strengths.” Eudaimonia has been transformed into a pluralistic psychological conception of self-achievement. Then, to be eudaimonic can take various forms and, at the extreme, each person has to discover her or his singular *daimon* and to develop it.

In that context, modern eudaimonic theories can serve to determine management responsibilities when it comes to employees’ work environment, tasks, career opportunities, and so forth. They advocate for managers having the duty to cater for employees’ self-realization and flourishing.

Two main reasons could justify such a duty. A first one is deontic. In the footsteps of Immanuel Kant, it could be argued that the respect due to employees *as persons* (which encompasses their interests, skills, etc.) requires to “use humanity, whether in your own person or in the person of any other, always at the same time as an end, never merely as a means” (Kant 1997, p. 38). This duty is reinforced in the case of individuals and institutions having a significant “social power” of affecting people’s life conditions (Davis 1960). Managers would have “socio-human” responsibilities toward employees, proportionate to managers’ capacity to interfere into employees’ lives, to help them to flourish.

A second reason is consequentialist. Relying on evidence asserting that employees who function well are more productive at work and, therefore, contribute more to the firm’s activities, the argument is to point the mutually advantageous situation created by eudaimonic management. Employees will feel more fulfilled by evolving in a context that better challenges their abilities and, as a result, they will help to build a more efficient organization (Harter et al. 2002).

Once clarified the justifications for managers’ duties, it is necessary to specify the forms that such duties could take. More precisely, it is important to determine the features of eudaimonic management: what principles would it follow and how?

For answering this question, one ought to adopt a stance on eudaimonia, that is, a psychological formulation of what eudaimonia is, what it entails, and how it can be pursued. There are several possibilities, and the most prominent

include the self-determination theory (Ryan and Deci 2017), psychological well-being (Ryff and Keyes 1995), personal expressiveness (Waterman 1993), and positive psychology (Seligman 2004).

These eudaimonic formulations share the fundamental idea that individuals, in order to flourish, function, or fulfill their potential, need to benefit from a specific context characterized by specific conditions. To that respect, the self-determination theory is emblematic. For individuals to flourish in their personal or professional life, three basic psychological needs have to be addressed: autonomy, competence, and relatedness.

Autonomy. Literally, it (*autos*-, self, *-nomos*, law) refers to the fact that individuals are their own source of normativity, they are self-regulating, viz. they are able of obeying to rules they have rationally endorsed. They need to feel in charge of their life, to sense that they are self-standing and have the faculty of taking decisions. In the professional realm, individuals need to have some mastery about how to organize their workload and tasks. To that respect, command and control forms of management undermine autonomy by imposing external pressure and decreasing the need for critical endorsement.

Competence. Individuals need to feel that their skills are properly used and recognized by their social networks. Moreover, they need to feel adequate, that is, they have a fair understanding of their environment and are able to pose acts that contribute in an efficient manner to their life and their environment. In work context, managers have a tremendous impact on how this is fulfilled. They can valorize employees’ competences and offer them adequately challenging tasks where they can grow and properly recognize their achievements. To the opposite, they can offer either not enough or too much challenging activities that will undermine one’s sense of efficacy.

Relatedness. Individuals need to feel socially included. It is about being part of a broader community to which one can contribute in a meaningful manner. To that respect, managers have a duty to foster a peaceful and

collaborative work environment where employees have the opportunity to socialize and find support when facing hardship and difficulties.

Overall, self-determination theory posits that individuals can be motivated by extrinsic or intrinsic aspirations. The former are external to the individuals. They are centered on materialistic values or rewards such as fame, money, prestige, and status. In contrast, the latter rely on internal rewards, that is, self-development and improvement. The self-determination theory claims that the three basic psychological needs are better fulfilled by intrinsic aspirations. Such motivations are stronger and reinforce one's sense of autonomy, competence, and relatedness. Intrinsic aspirations positively correlate to mental well-being while extrinsic aspirations are related to poor mental health (Kasser 2003).

Therefore, eudaimonic management is an umbrella term. It describes activities and settings crafted in order to support basic psychological needs' fulfillment by relying, as much as possible, on intrinsic motivations. Concrete implications are that along the traditional pay raises and status promotion, managers ought to design an environment where employees have a significant latitude for managing their workload, where their competences are properly put to use and stimulated, and where they feel included into their professional community.

To some extent, eudaimonic management could be seen as a manner of implementing corporate social responsibility within the firm. It also highlights the importance of a healthy corporate culture that is based on respect.

Summary

Eudaimonic management represents an attempt to apply to work relations the principles and lessons coming from well-being research. More precisely, its goal is to root management in eudaimonia, that is, to support the employees in adequately challenging their skills and

flourishing. In this sense, eudaimonic management sets socio-human responsibilities, which are justified by either the respect due to employees as persons or the mutual benefits created by a thriving workforce. Although there are many ways in which management could be eudaimonic, self-determination theory offers a clear framework and guidelines by positing the importance of fulfilling three basic psychological needs in order to have functioning employees. Those needs are autonomy, competence, and relatedness. For addressing them, managers and executives ought to rely more on intrinsic motivations than on extrinsic ones, that is, to increase the part of self-realization on one's abilities, proper recognition of one's talent, inclusion in a corporate community in comparison to material rewards (e.g., money) and prestige.

European Corporate Governance Institute (ECGI)

c/o the Royal Academies of Belgium,
Palace of the Academies,
Rue Ducale 1 Hertogsstraat,
1000 Brussels – Belgium
<https://ecgi.global/>
Email: admin@ecgi.org

Introduction

As explained on its website (ECGI [n.d.](#)), the European Corporate Governance Institute (ECGI) is an international, scientific, nonprofit association, founded in 2002 under Belgian law, which attempts to provide a forum for debate and dialogue between academics, legislators, and practitioners, on the main issues of corporate governance in order to promote best practices. It draws on the finest minds in academia from all over the world to tackle some of the most important issues that face businesses and governments

today. It uses the power of research to change ideas, influence practice, and formulate policy to benefit all of us.

History

Previously to its foundation in 2002, it was established on 15 October 2001 as an international scientific nonprofit association under Belgian law in accordance with its original Articles of Association (ECGI [n.d.](#)).

Through the initiative of ECGI directors and members, the European Corporate Governance Research Foundation (ECGRF) was launched in May 2016 (it was established in November 2013 by Belgian Royal Decree), with the main goal of providing the ECGI with sufficient funding and support to embark on a more ambitious and wide-ranging program of research activities (ECGRF [n.d.](#)).

Mission/Objectives/Focus Areas

The main goal of the Institute is to improve corporate governance through fostering independent scientific research and related activities. To that end, ECGI undertakes, commissions, and disseminates dominant research on corporate governance. Additionally, it can provide advice on the formulation of corporate governance policies and the development of best practices, as well as undertake any other action designed to improve the understanding and execution of corporate governance (ECGI [n.d.](#)).

By encouraging the interaction between several disciplines, such as economics, management, law, and finance, it serves as a useful reference for academics working on corporate governance-related issues in Europe and all around the world (ECGI [n.d.](#)).

Since its foundation in 2019, and thanks to the loyal support of its research members, institutional partners, patrons, and network of academic and practitioner members, the ECGI has achieved, among others, the following (ECGI [n.d.](#)):

- It has published more than 800 Working Papers on important topics.
- It has acquired nearly 600 members from more than 50 different countries.
- It has hosted over 20 international conferences and many workshops.
- It has provided training for 18 doctoral students.
- It has compiled a directory of over 460 International Corporate Governance Codes.
- It boasts three Nobel Laureates from among its founding members.

The ECGI maintains close links not only with all its institutional members but also with other organizations that are active in the field of Corporate Governance, such as the International Corporate Governance Network (ICGN) and the Global Corporate Governance Forum (GCGF).

Membership and Structure of Governance

Membership of the Institute is open to both individuals and organizations, and there are six categories of membership (ECGI [n.d.](#)):

- Institutional membership, which is opened to companies, institutions, and enterprises.
- Academic institutional membership, which is open to universities, business schools, or other academic bodies.
- Academic membership, which is open to individuals employed by or engaged in full- or part-time study in any accredited university or educational institution.
- Practitioner membership, which is open to private individuals and also to those in companies, institutions, and enterprises who wish to join in their own right.
- Patron membership, which is opened to legal entities or individuals interested in corporate governance. Patron members are patrons of the European Corporate Governance Research Foundation (ECGRF) and are appointed in

agreement with the boards of ECGI and ECGRF.

- Research membership, which is opened to individuals who have been appointed Fellows or research members by the ECGI.

The ECGI distributes the work of the research members through its extensive global network. On its website (ECGI [n.d.](#)), it offers extensive research reports, publications, and conferences free of charge, although payment is required for specific reports.

As far as the governance of the ECGI is concerned, it is headed by a Board of Directors, all of them being impartially committed to furthering the goals and mission of the Institute. Furthermore, in order to ensure the academic independence of the Institute, a majority of directors are drawn from academia. There are also directors closely linked to the private and public sectors. The Board Chairperson must be a non-academic and does not have to be a member of the Institute. The Vice-Chairperson, on the other hand, must be an academic.

At present, the Chairman of the Institute is the practitioner member Mr. Guy Jubb, Honorary Professor at the University of Edinburgh. He has played a leading role in developing and implementing best practice in corporate governance and stewardship in the UK and around the world. He was elected interim Chairman of ECGI in August 2018.

At present, the position of Vice-Chairperson of the Institute is waiting to be confirmed.

The Institute's current Executive Director is Dr. Marco Becht, Professor of Corporate Governance at the Solvay Brussels School for Economics and Management of the Université Libre de Bruxelles, the French-speaking University of Brussels.

As explained on its web page (ECGI [n.d.](#)), the ultimate authority is the General Assembly, which comprises all the Members of the Institute, each of whom has one vote. The powers of the General Assembly are detailed in the Articles of Association. It meets at least once a year, providing a forum not only for the ongoing governance of

the Institute but also an opportunity for members to meet, interact, and debate matters of importance and topicality.

A number of committees (the Research Committee, the Fellowship Committee, the Research Member Committee, the Research Member Engagement Committee) have been appointed to undertake specific functions of the Institute (ECGI [n.d.](#)). The actions recommended by these committees have to be approved by the ECGI Board and ultimately the members (ECGI [n.d.](#)).

ECGI Codes Database

The ECGI database provides an exhaustive compilation of codes, principles of corporate governance, recommendations, and corporate governance reforms in Europe and elsewhere (ECGI [n.d.](#)). It includes (Adams 2017) good governance codes promulgated at the country level and good governance codes promulgated at the international level, such as those of the Organization for Economic Cooperation and Development (OECD), the European Bank for Reconstruction and Development (EBRD), and the Commonwealth. For some countries it includes not only final versions of codes but also updates to the codes, proposals, draft codes, etc.

Definition

Generally speaking, Corporate Social Responsibility (CSR) is a type of self-regulation by business (Sheehy 2015). Public authorities, including both European Union (EU) member governments and European institutions, provide guidelines and, on some occasions, complementary regulation to support CSR implementation. The European Commission identifies CSR as the responsibility of corporations for “their impact on society” (European Commission [n.d.](#)). Corporations take the lead in implementing CSR norms through integration of “social, environmental, ethical, consumer, and human rights concerns into their business strategy and operations” (European Commission [n.d.](#)).

In terms of CSR policies and initiatives, the EU is the leading jurisdiction, as is evidenced by the publication of the *Green Paper: Promoting a European framework for Corporate Social Responsibility* (“the Green Paper”). As early as 2001, the EU took that role through the official launch of the CSR debates on a European scale in 2001. It has sustained this position through more recent efforts at exporting CSR values via its free

trade agreements. Over the past two decades, the EU has significantly contributed to CSR development (Idowu et al. 2015). Specifically, it has established a comprehensive CSR framework, both within the EU and externally in its interactions with non-EU trading partners.

Introduction

Corporate social responsibility (CSR) is a concept that has been around for quite some time (Sheehy 2015). Over the last few decades at the organizational level, CSR has evolved from “a nice thing to do,” to a strategic option, to an essential element for a successful business, a growing economy, a cohesive society, and a sustainable future (European Commission, n.d.; Association of Corporate Citizenship Professionals n.d.). At a society-wide level, CSR is now best understood as global business law (Sheehy 2015).

The European Union (EU) is the leading jurisdiction in terms of CSR policies and initiatives. The development of CSR in the EU has been driven by two key factors: proactive CSR strategies voluntarily adopted by corporations themselves, and external pressure from various stakeholders such as employees, investors, consumers, civil society, and public authorities (CSR Europe 2010).

Corporations are the ultimate implementers of CSR norms. Most EU corporations practice CSR, or at least some form of it, with a broad goal of mitigating negative impacts of their daily business activities and contributing to sustainable economic growth, social inclusion, and environmental protection (European Commission 2001). Public authorities, particularly under the leadership of EU institutions, that is, the European Parliament and the European Commission, have also played a critical role in initiating CSR debates, and promoting CSR practices.

The Private Framework

Literature on CSR first appeared in the 1930s when scholars debated about director's duties

and the social performance of corporations (Berle 1932; Dodd 1932). As could be expected, early CSR movements, both in Europe and elsewhere, were largely driven by corporations themselves (CSR Europe 2010). Corporations continue to play a critical role in CSR improvements. As the key actors and ultimate implementers of CSR principles, corporations adopt private or industry CSR standards, and build them into their business framework.

There are numerous CSR standards developed and adopted by the business sector; however, they generally address four main areas of responsibility: environmental responsibility, economic responsibility, philanthropic responsibility, and ethical responsibility, which includes human rights, labor rights, and social responsibility in a general sense (Stobierski 2021). In spite of these corporate efforts and investment, there is still a lack of both universally accepted CSR standards and a comprehensive framework. It is now broadly accepted that voluntary self-regulation is insufficient to achieve necessary outcomes given the wide spectrum of social and environmental issues that need to be addressed (The International Finance Corporation 2011).

Public authorities in the EU assumed a role as the main driver of CSR, adopting a two-layered approach. At the EU level, it has developed a comprehensive CSR framework. At the international level, the EU has been exporting CSR norms through the sustainable development (TSD) provisions of its free trade agreements (FTAs) (Hush 2018). The following sections examine the public frameworks established by the EU institutions, both within the EU and externally.

The Public Framework: Major CSR Developments at EU Level

The milestones of CSR development at EU level are as follows.

The EU institutions' CSR efforts can be traced back to 1999 when the European Parliament passed the *Resolution on EU Standards for European Enterprises Operating in Developing*

Countries: Towards a European Code of Conduct, and called for the establishment of a CSR framework that governs EU corporations' overseas business activities (European Parliament 1998).

In 2000, at the Lisbon Summit, EU heads of Member States made a pledge to “make Europe the most competitive and dynamic knowledge-based economy in the world, capable of sustainable economic growth with [...] greater social cohesion” (European Committee of the Regions n.d.). They agreed to make CSR policies an important priority of the “Lisbon Strategy” (Wouters and Chanet 2008).

In 2001, with the publication of the landmark *Green Paper*, the EU officially announced its commitment to developing a comprehensive CSR framework (European Commission 2001). This step is often seen as the starting point of the EU's CSR policies and initiatives (Tencati et al. 2004). The *Green Paper* outlined the EU's holistic approach toward CSR at both European and international level. It highlighted a range of CSR concerns, such as the environment and natural resources, labor standards, human rights, as well as other social concerns arising from business activities (European Commission 2001). Although corporations were the primary actors in terms of adopting management practices that reflect CSR values, the *Green Paper* called for collaboration by all stakeholders including corporations, social partners, public authorities, and civil society organizations, in an effort to promote CSR practices and to contribute to the improved governance of business (European Commission 2001). Extraterritorially, the *Green Paper* suggested that the EU could export CSR values through international and regional trade agreements (Jacur 2018).

In 2002, the European Commission published its first Communication on CSR: *Communication from the Commission concerning Corporate Social Responsibility: A Business contribution to Sustainable Development* (“the 2002 Communication”). As compared to the 2001 *Green Paper*, the overall view on EU CSR strategies remained largely unchanged (Wouters and Chanet 2008); however, the 2002 Communication took an important step forward by proposing to establish

“an EU action framework for CSR” (European Commission 2002). As part of this proposal, the EU Multi-Stakeholder Forum was launched to “improve the knowledge about CSR and facilitate the exchange of experience and good practice” between corporations as well as with their stakeholders (European Commission 2002). The 2002 Communication was known for laying “the foundation for a common understanding of CSR in Europe” (Mullerat 2013).

In 2006, the European Commission published its second Communication on CSR: *Implementing the Partnership for Growth and Jobs: Making Europe a Pole of Excellence on CSR* (“the 2006 Communication”). This Communication acknowledged that the EU needed “a public climate in which entrepreneurs are appreciated [...] for making a fair contribution to addressing societal challenges,” which in turn helps “inspire more European enterprises to go beyond their minimum legal obligations in favor of society and sustainable development” (European Commission 2006). The European Alliance for CSR (“the Alliance”) was created to “give greater political visibility to CSR” (European Commission 2006). Through this political initiative, the Alliance achieved two important goals. First, it helped leading EU corporations “develop[...] a series of practical tools on key issues” (European Commission 2011). Second, it helped develop a wider partnership involving not only corporations but also many more stakeholders. Strengthened dialogue and cooperation contributed to the identification of priority areas for EU action, including awareness-raising and best practice exchange, support to multistakeholder initiatives, cooperation with Member States, consumer information and transparency, research, education, small and medium-sized enterprises, and the international dimension of CSR (European Commission 2006).

In 2011, the European Commission published another Communication on CSR, *A Renewed EU Strategy 2011–14 for Corporate Social Responsibility* (“the 2011 Communication”), and stressed that improving CSR was in the interests of both corporations and society as a whole. Importantly, it stated that CSR was no longer “voluntary action beyond compliance” (Martinuzzi et al. 2011), but

“the responsibility of enterprises for their impacts on society” (European Commission 2011).

The 2011 Communication also unveiled an identification of the key challenges faced by the EU. As of 2011, some EU corporations had not fully integrated CSR norms into their business operations; a small number of EU corporations also allegedly violated labor rights and human rights. Furthermore, although more than half of the EU Member States had already developed nation-wide CSR strategies, action plans, or policy documents, the rest, predominantly Eastern European countries (Martinuzzi et al. 2011), still lacked “national policy frameworks to promote CSR” (European Commission 2011). To overcome these challenges, the EU highlighted eight priorities: enhancing the visibility of CSR and disseminating good practices; improving and tracking levels of trust in business; improving self- as well as co-regulation processes; enhancing market reward for CSR; improving company disclosure of social and environmental information; further integrating CSR into education, training, and research; emphasizing the importance of national, regional, and local CSR policies; and better aligning European and global approaches to CSR (European Commission 2011).

In 2015, the EU endorsed the United Nations’ Sustainable Development Goals (SDGs) (EUR-Lex n.d.) and somewhat problematically started referring to CSR as “sustainable development” (Sheehy and Farneti 2021). In the following year, the European Commission published another Communication, *Next Steps for a Sustainable European Future: European Action for Sustainability* (“the 2016 Communication”), and reinforced the EU’s commitment to sustainable development. The 2016 Communication developed two important work streams to support the implementation of SDGs. The first stream focused on policy development, particularly the integration of the SDGs into the broad European policy framework. The second stream aimed to develop forward-looking strategies based on reflection; specifically, it “prepar[ed] for the long-term implementation of the SDGs” beyond 2020 (European Commission 2016).

In 2019, the European Commission published the *Reflection Paper: Towards a Sustainable Europe by 2030* (“the Reflection Paper”). At EU level, the Reflection Paper reaffirmed that “the SDGs [were] endorsed at the highest EU political level,” and a monitoring and implementation mechanism was to be set up soon (European Commission 2019). At the international level, while consolidating policies at EU level, the report stated that the EU should put more effort into the establishment of international frameworks, particularly through trade agreements, multilateral negotiations, as well as working with international organizations (European Commission 2019).

Over the last two decades, the EU has made some impressive progress in creating an impactful CSR framework, both within the EU and externally, and it is striving to improve the system for a more sustainable future.

The Public Framework: The International CSR Framework

As noted, since the 2000s, the EU has taken a leading role in promoting CSR globally, and it has done so through introducing and institutionalizing CSR norms in the international trading system. All EU trade agreements negotiated since that time, often referred to as “New Generation” FTAs (Madner 2017; Makarenko and Chernikova 2020), incorporate explicit TSD provisions or dedicated TSD chapters to address broader CSR concerns. These provisions and chapters usually address environmental sustainability, labor standards, business-related human rights, and other responsible business conduct (Gantz et al. 2011; Harrison et al. 2019). This section describes how the EU has contributed to the establishment of an international CSR framework, with a particular emphasis on the EU’s innovations.

The EU’s program of exporting CSR values through FTAs began in 2000 with its geographically broad Cotonou Agreement—an agreement with African, Caribbean, and Pacific (ACP) states. This Agreement was significant because it marked

the beginning of the EU's endorsement of the concept of "sustainable development" in a trade agreement, addressing broader CSR concerns via the international trading system. In the Preamble of the Cotonou Agreement, the EU and the ACP states affirmed "their commitment to work together towards the achievement of the objectives of [...] sustainable development [...]" (Cotonou Agreement 2000).

The EU further strengthened its international commitment to CSR with the publication of the above-noted landmark *Green Paper* in 2001. What was significant in this regard was the EU's promotion of extraterritorial applications of CSR principles (Jacur 2018). The EU moved further ahead in the international CSR sphere by signing the Economic Partnership Agreement (EU-Cariforum EPA 2008) with the CARIFORUM states (LSE 2021). This agreement holds its first set of explicit TSD provisions in a trade agreement.

These provisions drew attention specifically to the importance of conforming to internationally recognized labor and environmental standards (EU-Cariforum EPA 2008). For example, Article 72 (b) requires investors to "act in accordance with core labor standards as required by the International Labor Organization (ILO) Declaration on Fundamental Principles and Rights at Work, 1998, to which the EC Party and the Signatory CARIFORUM States are parties" (EU-Cariforum EPA 2008). In 2010, the EU advanced its international CSR agenda further by signing an FTA with South Korea (EU-South Korea FTA 2011). This agreement stepped up the EU's CSR efforts by creating a dedicated TSD chapter and establishing a separate dispute resolution mechanism to ensure compliance. Since 2010, all EU FTAs have dedicated TSD chapters, with a broad scope of TSD norms; however, the main focus is on labor and environmental matters arising from business activities (LSE 2021).

TSD arrangements of the New Generation FTAs can be found in the EU's trade agreements with, for example, Central America, Ukraine, Georgia, Canada, Japan, Singapore, the United Kingdom, Moldova, Vietnam, Colombia, Peru, and Ecuador. These New Generation FTAs are an essential component of the EU's broad CSR

framework. Specifically, they supported and were an integral part of the EU's CSR broader initiatives, such as the *Trade for All* strategy (2015) which pushed for a more responsible trade and investment policy (European Commission 2015), the *15-point Action Plan* (2018) which focused on improving the enforcement of TSD rules, and the *Trade Policy Review* (2021) which considered further actions on effective implementation, particularly the "the possibility of sanctions" for violations of TSD rules (European Commission 2021).

To establish a more effective CSR framework at the international level, the EU has been pioneering new ideas in some of its most recently negotiated FTAs. The first innovation is the joint administration of the TSD implementation. The EU and its trading partners set out a procedure in FTAs for them to meet regularly and discuss how they can work collaboratively to improve CSR compliance. Recently concluded EU FTAs invite non-nation-state parties, such as civil society organizations, to get involved and provide social input to improving TSD rules and compliance, although traditionally non-nation-state parties are excluded from participation in these state-to-state dialogues and cooperation. For example, the 2016 EU-Canada Comprehensive Economic and Trade Agreement (CETA) successfully engaged non-nation-state parties in the administration of TSD chapters. Under the CETA, civil society organizations can contribute to TSD discussions through a joint Civil Society Forum (CETA 2016). This innovation is an important step forward as it enables members of civil society to share their knowledge, expertise, and experience that are particularly relevant to the legitimacy of the TSD rules as well as their implementation.

As for TSD dispute resolution, allegations of violations of TSD rules under existing EU FTAs cannot be brought through the legally binding general dispute resolution procedures (LSE 2021). They are subject only to voluntary dispute settlement mechanisms (DSMs) designed specifically to resolve TSD issues (LSE 2021). Under the multi-step voluntary DSMs, government consultation is the first step that parties can take to resolve a TSD dispute (LSE 2021). If the parties

fail to reach a mutually satisfactory resolution, they then move onto the next step: setting up a panel of experts to examine the matter (LSE 2021). The expert panel has no power to adjudicate; it only plays an advisory role and provides non-binding recommendations. In this context, it is then up to the parties to decide whether they will take the panel's advice, or have a further discussion based on the panel's recommendations (LSE 2021). If the parties choose to reject or ignore the panel's advice, they face no legal consequences. For example, articles 16.17 and 16.18 of the EU-Japan Economic Partnership Agreement (2019), articles 12.16 and 12.17 of the EU-Singapore FTA (2019), and articles 13.16 and 13.17 of the EU-Vietnam FTA (2019) all describe similar voluntary DSMs for TSD matters, particularly in relation to government consultations and panels of experts. This voluntary approach precludes the possibility of imposing legally binding trade sanctions on non-complaint parties, including in the event of serious TSD violations such as importing goods made with child or slave labor (LSE 2021).

Recognizing the weakness of the existing collaborative system, the EU has recently unveiled a new TSD approach to trade agreements. Based on a thorough review of the existing TSD provisions and their enforcement, the European Commission published a Communication: *The Power of Trade Partnerships: Together for Green and Just Economic Growth* in 2022. In this document, the EU proposed the imposition of trade sanctions on parties that breach core TSD provisions. This sanction-based TSD approach is to be applied to ongoing and all future FTA negotiations (European Commission 2022). Following this initiative, the EU-New Zealand FTA concluded in June 2022 made "the most ambitious sustainability commitments in a trade agreement ever" (Kelly and Doidge 2022). The new provisions have replaced the voluntary DSMs and are designed specifically to resolve TSD disputes with legally binding general dispute settlement procedures.

For example, Chapter 26 Article X.2 of the EU-New Zealand FTA states, "[this general dispute settlement procedure] shall apply with

respect to any dispute between the Parties concerning the interpretation and application of the provisions of this Agreement [...] unless otherwise provided in this Agreement" (The EU-New Zealand FTA 2022). In other words, in the event of serious violations of core TSD commitments, trade sanctions, such as temporary suspension of trade concessions, can be imposed as measures of last resort.

Summary

The EU has changed the environment in which EU corporations operate; it has also made significant contributions to global practice through its CSR leadership. It has done so through its forward-looking policy and steady development. Looking toward the future, it is clear that the EU has the ambition and ability to further improve responsible business practices both within the EU and internationally through its FTAs (Davidsson 2002). However, there are many obstacles still hindering the successful development and implementation of CSR norms. These challenges include the fact that not all EU members and not all EU corporations perform equally in terms of CSR compliance; and globally, ineffective compliance monitoring and enforcement mechanisms impede the effectiveness of the EU's TSD rules (Wagner 2017). The EU's CSR initiatives, while a good step, have yet to change corporate behaviors necessary to prevent the serious damage to the environment and the society as a whole that the world is facing (Chen & Sheehy 2023). Thus, although good initial steps, there remains a long road ahead.

Directive 2006/43/EC

Definition

The 8th Company Law Directive on Disclosure and Transparency (Directive 2006/43/EC) represents one of the main initiatives launched by the European Commission to enhance financial reporting' transparency. In detail, the Directive 2006/43/EU introduced a first set of rules to harmonize auditing procedures at the European level. Building on the main issues identified by academics and practitioners, the Directive identified a set of minimum requirements to enhance the overall quality of assurance processes, which represented one of the main criticisms identified during the initial phase of accounting harmonization in Europe. At the same time, the Directive also introduced additional ethical and professional requirements to raise the quality of the control processes adopted by the external auditors.

Auditing Harmonization in Europe

Since the second half of the twentieth century, the European Commission have considered accounting harmonization as one of the main goals to achieve. Accounting harmonization represents a strategic driver for the development of the European financial market because of the opportunity to favor the exchange of reliable and comparable information between companies and users. In this regard, many initiatives were launched to identify a common taxonomy to enhance the quality of the accounting processes (Nobes and Parker 2010). Within this scenario, the most relevant directives for accounting unification were the IV and the VII. The two directives, respectively, contributed to the debate through the introduction of more stringent requirements regarding the substance and form of financial statements (IV Directive) and through the definition of an organic set of rules on consolidated financial statements (VII) (Adamo 2001). Furthermore, in 1995 the process of accounting information received a new impetus as a result of the initiative taken by the party of the International Organization of

Securities Commissions (IOSCO), which started an initial discussion with the International Accounting Standards Committee (IASC) regarding the identification of appropriate accounting standards to be applied in the context of multinational companies (Murphy 2000).

The need to identify a set of common metrics to disclose financial information impacted also on auditing processes. In fact, an effective accounting harmonization requires also a subsequential analysis of the main issues related to auditing processes, which represent the main tools used by practitioners to verify the reliability of the information disclosed by companies. Considering that criticism, the European Commission launched two preliminary initiatives to integrate European regulation with specific rules about auditing processes:

- 15 November 2000: Recommendation on quality assurance for the statutory audit in the European Union: minimum requirements.
- 16 May 2002: Recommendation on Statutory Auditors' Independence in the EU: A Set of Fundamental Principles.

The two initiatives were followed by the publication of the final draft of the Directive 2006/43/EC in June 2006, which established rules concerning the statutory audit of annual and consolidated accounts (European Commission 2006). The Directive introduced substantial and formal requirements for auditors, such as the provision of more strict criteria in terms of educational background, professional knowledge, and practical training. In detail, the Directive 2006/43/EC consists of 55 articles and by the following 12 chapters:

- Chapter I — Subject Matter and Definitions
- Chapter II— Approval, Continuing Education and Mutual Recognition
- Chapter III — Registration
- Chapter IV — Professional Ethics, Independence, Objectivity, Confidentiality and Professional Secrecy

- Chapter V — Auditing Standards and Audit Reporting
- Chapter VI — Quality Assurance
- Chapter VII — Investigations and Sanctions
- Chapter VIII — Public Oversight and Regulatory Arrangements Between Member States
- Chapter IX — Appointment and Dismissal
- Chapter X — Audit Committee
- Chapter XI — International Aspects
- Chapter XII — Transitional and Final Provisions

Although the introduction of a wide number of items, the main novelties identified by the 8th Directive can be summarized in the 8 clusters identified by Tiron-Tudor and Boța-Avram in their pioneer research published in (2013). According to the authors, the main novelties of the Directive consist of the new requirements about confidentiality and professional secrecy of client information, public oversight over statutory auditors, audit quality assurance, independence and objectivity of the statutory auditors, disclosure of audit fees, audit firm transparency, auditing standards, and audit committees.

In the last few years, the Directive 2006/34/EU has been updated by the European Commission. In 2014, the European Union adopted a relevant reform of the EU Statutory Audit Market through the publication of two legal instruments: the Directive 2014/56/EU amending Directive 2006/43/EC on statutory audits of annual accounts and consolidated accounts (the Audit Directive) and Regulation No 537/2014 on specific requirements regarding statutory audit of public-interest entities (the Audit Regulation). The aims of the reform could be synthesized in four different needs: enhancing transparency, reinforcing auditors' independence, promoting competition between Big4 and small auditors, and strengthen pan-EU supervision. In this regard, the current debate about auditing harmonization in Europe is characterized by an increasing attention paid by academics about the main initiatives and consultations launched by policy makers and standard setters (Krivogorsky 2011).

Summary

Harmonization is a key topic in accounting research. However, only a few parts of accounting literature consider the main implications related to auditing harmonization, which represents a standalone topic in accounting research. In this regard, the analysis of the Directive 2006/43/EC represents a key pillar for an effective comprehension of the real effects related to the introduction of more strict requirements by Member States. Within this scenario, accounting scholars could cover a pivotal role to bridge the knowledge gap between academia and practitioners.

Event Studies

Lars Schweizer and Eva Maria Katharina Koscher
Goethe-University, Frankfurt am Main, Germany

Description

The so-called event study is a statistical method. It is commonly used to evaluate the influence of a specific event on firm value (MacKinlay 1997; McWilliams and Siegel 1997). An example would be the announcement of a mass layoff. With the help of an event study, it can be analyzed if investors believe this layoff creates or destroys firm value. Other events often analyzed with the event studies include mergers and acquisitions (M&A), earnings announcements, investment decisions, or corporate social responsibility-related issues (MacKinlay 1997; McWilliams and Siegel 1997).

In an event study, the actual observable returns to a company given an event are compared to return predictions (the assumed returns that would have been achieved if no event had occurred). Any difference is attributed to the event under investigation. Introduced by Dolley (1933) and mainly influenced by Fama et al. (1969), the event study method has become the standard way of measuring stock price reactions to some announcement or event (Binder 1998). The wide variety of possible applications has

made the event study method commonplace in economic, finance, and accounting research, and the number of empirical studies using this method is huge.

Introduction

The event study method is founded on the assumption that markets are efficient (efficient market hypothesis or theory). The underlying efficient market theory is one of the dominant themes in academic and financial economics literature since the 1960s (Elton et al. 1995). It states that “*security prices at any point in time “fully reflect” all available information*” (Fama 1970, p. 388). According to this hypothesis, security prices provide an unbiased estimate of the discounted value of a firms’ future cash flows. Furthermore, they accurately reflect all available information if the financial market is efficient in its ability to absorb information relevant to the value of stock prices and security prices as they instantly adjust to new information (Fama 1991; Fama et al. 1969; Harrison and Freeman 1999).

Since this is evidently an extreme null hypothesis, Fama (1970, 1991) distinguished three different types of market efficiency: the weak form, the semi-strong form, and the strong form efficiency. In the weak form, the efficient market theory states that current prices on traded assets (e.g., stocks, bonds, or property) already contain all information given by historical prices. To fulfill the necessities of the semi-strong form of efficiency, it is mandatory that current prices on traded assets contain all information given by historical prices, fully reflect all publicly available information, and change very rapidly to the new publicly available information. Finally, strong form efficiency additionally demands that current prices on traded assets reflect all information, public and private. The overall idea behind the event study method is to attribute abnormal returns (defined as the difference between actual observable returns and expected ones) to an event (Binder 1998). Thus, the event study method can

be used to investigate stock price reactions as an answer to the announcement of unforeseen events (Fama et al. 1969). The event study method is based on the assumption that capital markets are semi-efficient, i.e., that there is a fast reaction of capital markets to the new publicly available information.

In academic literature, different ways of conducting an event study are used and debated (Bowman 1983; Peterson 1989; Santomero 1991; Strong 1992). However, management research usually follows the recommendations of McWilliams and Siegel (1997) and MacKinlay (1997) concerning the design of an event study. Therefore, this standard method for conducting an event study is outlined below.

Method Explanation

The publication day of an event under investigation is taken as the event or announcement date. In case there were several announcements for the same event at different points in time, the earliest announcement encompassing the relevant information is defined as the announcement date. If the announcement date cannot be identified with certainty or if there were only speculations, but no specific announcements, an event should not be taken into account. The time around the announcement date, the so-called event window, is used to measure abnormal returns. It is often starting the day before the announcement date and ending on the day after the announcement date (3-day event window). It is important to keep in mind that both the precise determination of the announcement date as well as the length of the event window influence the quality of an event study. Since the event window length is inversely linked to the quality of the results (Brown and Warner 1985, p. 12), MacKinlay (1997) postulates that a 2-day event window is sufficient to incorporate all relevant information and at the same time mitigates the appearance of noise (e.g., because of overlapping events). Therefore, the event window often only includes both the announcement day ($t = 0$) and the next day ($t = +1$), reflecting the ideal event window

length recommended by MacKinlay (1997). If overlapping events are observed within the event window of a specific event, an event should be deleted from the sample to ensure accuracy of the data.

Selection of Normal and Abnormal Returns and Test Statistics

Usually, discrete returns are used to estimate the expected returns of the stocks under investigation. All deviations of the observed returns from the expected returns, which are presumably caused by stock-influencing information (e.g., the announcement of employee layoffs), are interpreted as abnormal returns (McWilliams and Siegel 1997). In other words, the abnormal return is the difference between the actual ex-post return of a security over a selected event window and the security's expected return over the same event window (MacKinlay 1997). The abnormal return can be calculated, and this is mostly done using the market model. The equation for the abnormal returns is as follows:

$$AR_{i,t} = R_{i,t} - E(R_{i,t} | X_{i,t})$$

with $AR_{i,t}$ as the abnormal return of the security i on day t , $R_{i,t}$ as the return of the security i on day t and $E(R_{i,t} | X_{i,t})$ as the expected return of the security i on day t for when considering the estimated market model.

The market model outlined by Sharpe (1963) is usually taken to calculate the expected returns. The equation is given as follows:

$$R_{i,t} = \alpha_i + \beta_i * R_{m,t} + u_{i,t}$$

with $R_{m,t}$ as the rate of return on a market portfolio on day t , α_i as the parameter of the market model, β_i as the systematic risk of security i and $u_{i,t}$ as the error term. The needed parameter estimates of the market model can be obtained from regression analysis over an event preceding the estimation period.

Once the market model parameter estimates are obtained, it is possible to calculate the abnormal returns of security i on day t by subtracting the expected return within the event window from the actual return within the event window. The

following equation (Brown and Warner 1985) needs to be used:

$$AR_{it} = R_{it} - \hat{\alpha}_i - \hat{\beta}_i * R_{mt}$$

These calculated abnormal returns are now assumed to echo the stock market's reaction to the announcement. In the next step, the abnormal returns calculated for each company for each day around an event are taken to calculate the average cumulative abnormal returns $\overline{CAR}_{(t_1, t_2)}$ for the event window (time period (t_1, t_2)) for the whole sample. The equation is given by Fama et al. (1969) as follows:

$$\overline{CAR}_{(t_1, t_2)} = \frac{1}{N} \sum_{j=1}^N \sum_{t=t_1}^{t_2} AR_{it}$$

With $\overline{CAR}_{(t_1, t_2)}$ as the average cumulative abnormal returns during time period t and AR_{it} as the abnormal return of stock i on day t. After the CARs have been computed, statistical tests should be used to assess whether or not the average cumulative abnormal return differs significantly from zero. The test hypothesis is given as follows:

$$H_0 : E(\overline{CAR}_{(t_1, t_2)}) = 0 \quad \text{vs.} \quad H_1 : E(\overline{CAR}_{(t_1, t_2)}) < > 0$$

To test for the significance of the calculated abnormal returns, one can use parametric tests (t-tests) or a non-parametric test (Wilcoxon Sign Rank).

Event Study Tools and Implementation

Event studies are often implemented and analyzed with the help of statistical analysis software (e.g., Stata, Matlab, or R). In addition, apps and desktop tools which help to perform event studies exist (e.g., <https://eventstudytools.com/> or <https://eventstudymetrics.com/>).

Summary

The overall idea behind the event study method is to attribute abnormal returns (defined as the

difference between actual and expected returns) to an event (Binder 1998). In general, an event study is a systematic examination of the average impact of a certain event on the price of a particular type of (corporate) asset. Event studies constitute an established research method among researchers in the fields of accounting, finance, management, and marketing. The standard event study method employs a 2–3 day event window and uses the market model of Sharpe (1963) to calculate the expected returns.

E-waste

Abhijit Roy
Department of Marketing, Howard University,
Washington, DC, USA

Synonyms

[Electronic waste](#)

Definition

E-waste or electronic waste is any electrical or electronic equipment that has been discarded, including working and broken equipment tossed in the garbage or donated to a charity store. These are hazardous since the toxic chemicals that innately percolate from the buried metals are very harmful to living organisms. Over 60 million tons of e-waste is currently created every year, equivalent to all of the business airlines ever manufactured. In 2022, the total e-waste output would be equivalent to more than 400 cruise ships. If all of the e-waste of the world in a given

year would be placed in a line, it would be over 77 miles long, and it would take over an hour of highway driving to get to the end.

Only a less than a fifth of it is recycled. This form of waste is worse than other types since the materials needed to make them are usually toxic and hazardous and are likely to pose risks to individual's health and security and the environment. After discussing the various types of e-waste, statistics of the growth of e-waste are provided, followed by the discussions of the major ordeals, disposal options, and a conclusion.

Types of E-Wastes

There are many types of E-Wastes. With the proliferation of technology, their variety continues to grow. Some of the major examples under the primary categories are as follows:

Communications and IT Devices

Smartphones, desktop and laptop computers, monitors, circuit boards, and hard drives

Electronic Utilities

Electrical cords, Fitbits, heating pads, heart monitors, lamps, massage chairs, night lights, smart lights, smart watches, television remotes, and treadmills

Home Appliances

Electric cookers, fans, heaters, home entertainment devices, and microwaves

Home Entertainment Devices

Blu-ray players, copiers, DVDs, fax machines, printers, stereos, televisions, and video game systems

Office and Medical Equipment

Audio and video equipment, autoclave, copiers and printers, cords and cables, defibrillator, dialysis machines, imaging equipment, IT servers, network hardware, phone and PBX systems, power strips and power supplies, Wi-Fi dongles

Growth of E-Waste

Over 60 million tons of e-waste is currently created each year – according to Statista (2022); the amount has steadily increased from 33.8 million tons in 2010 to over 60 million tons today and is expected to be almost 75 million tons by 2025 (see Fig. 1). The e-waste produced annually is worth over \$62.5 billion, more than the nominal GDPs of nearly half of the countries in the world.

As shown in Fig. 2, as of 2020, Asia produces the largest volume of e-waste (23 million), followed by the Americas (North and South) (12 million tons), Europe (11 million tons), Africa (3 million tons), and Oceania (1 million tons). Yet, per capita, Europe produces the most e-waste at 35.6 lb. per person, followed by Oceania (35.4 lb.), and the Americas (29.2 lb.). Asia and Africa's per person contributions are much lower at 12.3 lb. and 5.5 lb., respectively.

Even though the advanced nations create the most e-waste, between 70% and 80% of the world's e-waste (equivalent to between 3 and 9 million tons) is sent to the landfill sites in developing nations, where it is sorted and sold or burned to extract materials. The world's largest e-waste scrapyards are in Agbogbloshie, an area in Accra, Ghana. It receives over 225,000 tons of e-waste every year.

E-waste grew at a rate of 21% a year between 2014 and 2020. Based on current trends, the total amount of e-waste will reach 74 million tons, nearly doubling the output from 2014.

Ordeals with E-Waste

With the proliferation of electronic devices, the three major problems with e-waste are the potential harm that they do to the environment, our health, and data security issues. They are discussed below.

Environmental Hazard

If not disposed properly, e-waste can be harmful to the environment, since it can contain toxic materials such as lead, mercury, and cadmium. These

materials can leach into the soil and water supply if e-waste is not properly handled, causing damage to ecosystems and potentially posing a risk to human health. Hence, they need to be properly disposed so as not to harm the environment.

Specifically, the environment can be harmed in three primary ways:

- *Air contamination:* The shredding and melting of e-waste releases dust particles in the atmosphere and causes increased pollution. In 2020, nearly 90 million tons of carbon dioxide contaminated the atmosphere from refrigerator and air conditioning e-waste alone, contributing to nearly 0.3% of global greenhouse emissions that year.
- *Soil contamination:* The improper disposal of e-waste in landfills causes heavy metals and flame retardants to seep directly into the soil. A computer and a monitor require 500 lb. of fossil fuels and 50 lb. of chemicals, which contaminate the soil if not disposed properly.
- *Water contamination:* Heavy metals can leak from the soil to the groundwater causing severe damage through acidification and toxification.

Health Hazard

The e-waste also releases greenhouse gases harming human health, as well as that of wildlife. It particularly harms the health of people living or working close to the e-waste recycling sites. This is especially true of sites around developing countries. There are over a thousand harmful substances including nickel, lead, and mercury. Health problems include changes in thyroid function, adverse neonatal outcomes, temperamental and behavioral swings, and diminished lung functions.

Individuals exposed to e-waste are at greater risk of stillbirths, premature births, and spontaneous abortions and are more likely to have greater DNA damage. Their children are typically shorter and have reduced birth weights. There are currently over 18 million children and adolescents working in the e-waste processing sectors. The toxic chemicals in e-waste typically cause them to be of smaller size, and have less developed organs.

E-waste, Fig. 1 E-waste generated worldwide from 2010 to 2019 and projected between 2019 and 2030 (in million metric tons). (Source: Statista (2023))

Data Security

If not disposed properly, critical documents and serial numbers may be used by miscreants for stealing someone’s identity. For both businesses

as well as individual consumers, care must be taken to discard the hard drive in one’s computer or the memory stick in a smartphone. Although several disposal methods exist, none are as

E-waste, Fig. 2 E-waste generation by country (2020) [in thousand metric tons]. (Source: Statista (2023))

foolproof as physically destructing or dismantling the electronics equipment. One must, however, be careful, since many of these devices are likely to explode if dismantled incorrectly. Businesses should be particularly careful about protecting their customers and employees' data because of harsh legal liabilities.

independent e-waste recycling firms that take responsibility of handling the disposal of old electronic devices. A third option is to donate e-waste to organizations that can reuse or repurpose the equipment. Several nonprofit organizations, schools and other institutions, and libraries look to using the donated electronics either as is or after repair.

Disposal and Recycling Options of E-Waste

It is critical to properly dispose of e-waste to prevent harm to the environment, and to ensure that valuable materials are recovered and reused. By properly managing e-waste, the environmental impact of electronic devices can be reduced, hence promoting sustainable resource management.

There are several modes of properly disposing of e-waste. The best option is to recycle e-waste at certified facilities. Most major electronics manufacturers and retailers offer e-waste recycling programs. Additionally, there are

Summary

The world is beginning to have a much greater appreciation for the management of e-waste. Switzerland initiated the first e-waste program in 1991 with the introduction of a system to recycle refrigerators, and soon adding many more electronic devices to the list. By the turn of the twenty-first century, the European Union had adopted similar e-waste recycling programs for member nations.

Most countries in the world have now followed in their footsteps. Global organizations such as the UN agencies, the World Economic Forum, the

Global Environment Facility, and the World Business Council for Sustainable Development have continued to push for a continued revamping of laws governing the disposal of electronics products. In the USA, even though there are no federal laws governing e-waste, over half the states have enacted their own e-waste laws. Most major retailers in the USA and elsewhere have generous e-waste recycling policies regardless of where the product was bought.

With the annual value of e-wastes being greater than the GDP of many countries – now totaling over 7 kilograms for every person on the planet or the equivalent in weight to all the commercial aircraft ever built, disposing them properly has become imperative. Nearly 80% of e-waste is improperly disposed, much of it in developing countries. That needs to change because of health, pollution, and security impacts as well as a loss of scarce and valuable raw materials.

Members of the *UN E-Waste Coalition* including *UN Environment*, *Global Environment Facility*, the *World Economic Forum*, and the *World Business Council for Sustainable Development* have called for an overhaul of the e-waste disposal system underlining the need for a circular economy where resources are valued and reused so as to minimize environmental impacts and create good sustainable jobs.

Executive Remuneration and CSR

Laxmi Remer

CBS International Business School, Cologne, Germany

Synonyms

Bonuses; Executive compensation; Executive pay; Executive salaries; Pay packages; Stock options

Definition

The financial payments and benefits (the complete package) paid to high-ranking executives of a company as compensation for their respective jobs conducted for the company are widely termed as executive remuneration. The said high-ranking executives often bear the designations of president, vice-president, senior director, chief (executive, operating, financial, or treasury) officer, managing director, etc. among others.

The different components of the executive remuneration include:

- Base salary
- Bonus
- Stock options
- Stock grants (restricted stock plans)

- Pension
- Benefits (car, healthcare etc.)
- Perquisites (perks – like driver, company airplanes, etc.)

Base salary is the initial rate of compensation – usually based on the position which usually takes into account education and qualifications.

Bonus is an annual compensation based, if not completely then partly, on performance of the company. It is an incentive for managers to achieve (usually) quantitative targets such as increased revenues or profits or earning per share (EPS), etc. The incentive can also be turning a company around or a new corporate strategy, etc.

Stock options are most often offered to the managers to align the interests of shareholder and managers. The aim originally was to alleviate agency conflict. However, it has been seen that stock options have the tendency to fuel short termism in the decision-making process.

Stock grants are restricted stock plans whereby the liquidation of the stocks is staggered so as to ensure relatively longer-term commitment of the managers.

Pension is the payment paid out periodically to the employee when the said employee retires. It is a fund into which the employee, the employer, and the state may add sums of money over the employed years.

Benefits and perks are sometimes used as synonyms and are all the other extras that are added to the remuneration package, such as vehicle, accommodation, first-class air fare or charter services, etc.

Background

Executive remuneration is discussed widely and regularly and is in the dock because of the (perceived) excesses. The executive compensation has and should justifiably be higher than that of a worker. The reason is that the responsibilities of these two positions differ dramatically. The current divide between these pay positions is

however very debatable. The ratio of CEO-to-worker pay in 1965 was 20:1. In other words, for every dollar that a worker made, the CEO made \$20; in 1995, the ratio was 123:1, and in 2017, it was 312:1 (Mishel & Schieder, 2018).

The dramatic and steep hike in executive compensations is driven by stock-related payments. Stocks or shares carry a certain risk and therefore need to be compensated for. Despite accounting for this, the level of executive pays has defied gravity. Post-financial crises, from 2009 to 2018, median CEO pay of S&P 600 companies increased 95%. Using the same yardstick, for the same period, the median worker's pay rose by 20% (Roe & Papadopoulos, 2019).

Substantial bonuses, to the tune of \$20 billion, drawn from the bailout funds were paid out to themselves in 2009 by the Goldman Sachs, AIG, Bank of America, and Merrill Lynch among others, prompting President Obama to call the financial institutions “shameful” (Story & Dash, 2009). Nine banks that together lost \$81 billion received the biggest chunk of bailout funds to the tune of \$32.6 billion. These banks then paid some of their traders and bankers about \$one million each in bonuses (Story & Dash, 2009).

What happened to the bailout funds given to those who were partly responsible for the financial crises has been a textbook example of moral hazard at its best. The fact that most ordinary people will now have to take a cut in their retirement pensions and/or have to work way long past their retirement ages to make ends meet has fueled the outrage toward excesses of the boardroom. This justified anger led to calls of wider regulation on executive compensation in the USA.

This resentment was not limited to the USA. Hardline stance on executive compensation was also adopted by France and in Germany (Moffett, 2009; Inman, 2009). Backed by the EU Parliament, France, German, Italy, Luxembourg, the Netherlands, Spain, and Sweden jointly called for a ban on all guaranteed bonuses and deferral of all other bonuses over several years. Germany and France have also brought in rules to cap and tax bonuses in a move to reform the banking

sectors (Collins, 2009). In the UK, the government in 2009 announced that a one-time 50% corporate tax on all banking bonuses above £25,000 would be imposed (Spanier & Tobin, 2010).

Justification of High Salaries

On a year-on-year basis, there is a distinct ratcheting up of the executive compensation. This can be due to many reasons.

The argument that is most omnipresent in justifying high salaries to the executives is that, to attract and retain good caliber, one has to hang a good carrot. To retain good people is supposedly very difficult since they get head hunted or are tempted by better offers. Companies therefore offer very attractive pay packages so that their top executives resist the temptation to go elsewhere.

Another argument that is used to justify high pay is the “top of the industry” claim. If a company is a market leader, then it needs the right talent to maintain this leadership position. This is because at this level, even a minor slip-up can be very expensive. A CEO who is well versed with the product and financial markets and with strategizing and has charisma, personality, and the courage to lead a company will of course not come by cheap.

Another oft-cited reason is the “peer group” practice. This is fairly common in the industry. Here, when deciding upon the compensation for top executives, businesses of similar type and size are used for setting up the peer group. The compensation paid out by this peer group is then used as a benchmark to decide upon the compensation package for the said top executives. A matched package, if not better, is the usual outcome of such peer group analysis. Interestingly, in reality, it is very common to have bigger companies in the peer group – causing at times big hikes in executive pays.

Yet another reason is simply hiking up of the bonuses when top executives change their job from one big company to the other.

Executive Remuneration and CSR

The size of executive compensation and the serious divide it leads to in the society are causes for concern. There are many arguments provided by the industry that such high remuneration is justified and there are equal arguments which insist that the disparity between a worker’s pay and an executive’s pay is totally unjustified.

However, it is clear that the level of pressure at the very top of the company is way different from that on the shop floor. The top executives are not only responsible for themselves but for the whole company. Wrong decisions can cause severe consequences on all stakeholder levels which also includes many a times the economy itself. Unlike a worker who can usually go home at the end of the working day, the top executive is never really free from the organization given his/her responsibilities. This in many ways allows for the higher level of compensation.

The issue is not that the compensation is high but that it is “too” high. Unfortunately, it is very difficult to pin the right figure for compensation, and several efforts have been made on both the company and regulatory levels to rein in the excessive pay packages. Shareholders have also been encouraged to use their “say on pay” to curb the excesses.

While it is only fair that consistently good company performance and added value to the shareholders should be rewarded commensurately, it is also fair to prevent serious disparity of pays. The responsibility of a company is to maximize its shareholder wealth while upholding its social and ethical responsibilities. In this particular context, it can only be achieved if the executives at the top accept their responsibility toward proactively limiting the relentless ratcheting up of remuneration to prevent the serious disparity.

Synonyms

External costs; Market failure; Side effects; Spill-over effect

Definition

Externalities are positive and negative side effects that come from producing or consuming a good or service. The effect is not brought about by those affected. The affected third party – an individual or an organization, or society – has no control over the creation of that cost or benefit, as externalities are associated with the cause–effect chain.

Externalities as a Phenomenon

Henry Sidgwick (1901) was the first economist to articulate the “spillover effects” of production and consumption. After him, Arthur C. Pigou (1932) formalized the concept of “externalities.” Pigou’s externality theory was dominant in economics until Ronald Coase published “The Problem of Social Cost” (Coase 1960). Externality dominates the theory of economic policy (Buchanan and Stubblebine 1962).

The idea of a market economy is based on smart and rational consumer choices. These choices guide markets toward the best outcome. However, in the current global economy rational choices are difficult to make as producers and consumers are located far from each other. Long product manufacturing chains include externalities that are not reflected in the prices of products and services and whose existence is difficult to identify. For example, in Europe, a large proportion of daily commodities are made in Asia.

Market failure may occur if the prices of products and services do not tell consumers the truth. The price of a good or service gives a distorted message to the consumer. Maximilian Auffhammer states that the slow response to climate change is “the biggest environmental market failure in human history” (Auffhammer 2018, p. 33). Even if the cost of climate change to society is difficult to determine, worldwide perspective on Arctic change reveals that releasing of methane from permafrost has an average global price tag of 60 trillion USD in the absence of mitigating action (world economy in 2012 was 70 trillion USD). Vast majority of the cost will be paid by developing countries. They will face extreme weather, lower agricultural production, and health problems (Whiteman et al. 2013; Cook et al. 2013).

There are technological and pecuniary externalities. Polluting of the water supply is an example of the technological externality that affect people in non-market way. Opposite to this, pecuniary externalities occur through the market. A new industry may reduce the value of capital by capturing customers of the other employers. Also, it may raise labor costs for other employers in the area (Hashimzade et al. 2017).

Positive and Negative Externalities

In Finland the saying “money smells” refers to the positive and negative effects of having a paper mill in your local area. In European Union, cycling provides annual benefits worth 24 billion euros, and walking around 66 billion euros, respectively. Opposite to this the annual social cost of automobility is 500 billion euros (Gössling et al. 2019). Thus, mobility presents both positive and negative externalities for society and citizens.

A positive externality causes an indirect benefit to an individual, an organization, or society. For example, planting trees makes people’s properties more attractive while also reducing air pollution (Mayhew 2015). An example of a positive externality might be growing apple trees, which also provide a good source of nectar for honeybees, thus benefiting the beekeeper (Manley et al.

2019). Thus, positive externalities are the effects of an activity that are pleasant or profitable but for which no price can be charged, such as the fertilization of fruit trees by bees.

Negative externality causes an indirect cost to an individual, an organization, or to society, “which does not have to be paid for by those carrying out the activity” (Hashimzade et al. 2017). An example of a negative externality could be, for instance, where pollution from an industrial plant impacts agricultural land, damaging plant life and affecting the livelihood of farmers nearby (Manley et al. 2019). Another common example is toxic emissions from industrial plants, where the people in the surrounding area that are harmed by the emissions have to bear a cost to mitigate the harm caused to them (Mayhew 2015). There is, however, “no externality until the law gives the cost bearer a right to be free of the costs imposed” (Adelstein 2017).

Toward a Transparent, Real-Cost Economy

Much of the true cost of the material well-being of people living in industrialized countries is outsourced to the soil, the atmosphere, people at the bottom of product processing chains, and especially to future generations. Social costs increase injustice in the world because the disadvantages of producing a particular product may only affect those who do not use the product or otherwise benefit from it. At the global level, the pollution of the workers’ working environments is already more harmful than malaria (Mills-Knapp et al. 2012). In other words, the price of many products and services is too low, because the social costs that come from producing or consuming a good or service are not included in the price (Parry et al. 2014). This leads to market failure. According to van den Bergh (2012) “system complexity, lock-in, and bounded rationality mean that the mainstream economic view of externality regulation is not accurate.”

In a society, sustainability transformations are easier to implement if all products and services in

the economy correctly reflect their indirect environmental and social impacts. This can serve to guide the daily decisions of consumers, producers, investors, and innovators toward sustainability (van den Bergh 2012). For example, when extracting, transporting, and processing coal, a waste stream is generated. Together with combustion these externalities are linked to multiple health and environment hazards, whereas the external costs of genuinely renewable sources of energy, such as wind and solar power, are remarkably lower. In 2005 terms, the greenhouse impacts and health damage costs of different power generation technologies in Europe were (Biegler 2009; also Castleden et al. 2011):

- 58 eur/MWh for brown coal
- 41 eur/MWh for black coal
- 4 eur/MWh for nuclear power
- 0.9 eur/MWh for on-shore wind power

It is usually argued that governments should take steps to eliminate negative externalities by means of taxation or other penalties. Transparent pricing, including the social costs and benefits of producing and consuming goods and services, is an essential solution for a rational market economy where citizens’ choices eliminate bad solutions and allow good solutions to thrive. The costs of pollution and depletion of natural resources due to the production and consumption of products can be more fully integrated into product prices, for example, through sin taxes. Pigouvian tax, for example, discourages “activities that impose a net cost of production onto third parties and society” (Pigou 1932).

Externalities in the Future

When externalities are identified, the negative externality can be decreased, and the positive externality increased. However, if people are not aware of the externality, they will not see the need to do anything about it (Horowitz 2013). For example, giving birth induces both positive and negative externalities. Many current tax, welfare, and school policies subsidize children. If

emissions restrictions are imposed, there may be pressure to make population policy less pronatalist, as the induced population externality is generally large. In theory, the optimal population is achieved through a planning policy “that can be implemented with emissions taxes (or caps) and child taxes” (Bohn and Stuart 2015). The issue is sensitive, and it is related to climate anxiety.

In a society, the role of claim-makers is essential. They persuade others that something is an externality. According to Best (1989) “claim-makers may be social movement activists, company representatives, scientists, members of the mass media, politicians, teachers, or anyone who has a bumper sticker, signs petitions or through conversation supports a cause.” What is an externality depends on the information that people have.

Companies are responsive to customers’ demands because their profitability depends on them. The power of consumers is increasing as people have more information available and more opportunities to share information. A single positive or negative observation can fast gain global attention. As this awareness increases, ecologically and socially unsustainable businesses lose their competitive edge. This was not possible on such a large scale before the current opportunities presented by social media.

Eliminating the negative externalities of a business may require transforming the entire production or service process. Increasing awareness of our planet’s finite resources and of mounting inequality is changing consumer behavior. The importance of low price as the sole determinant of consumer choice has already started to dwindle in well-being societies (Salonen et al. 2014). A way forward is offered by circular economy, as exemplified by collaboration in nature: “Bees require nectar from plants, and plants require pollination. So when plants were producing nectar and did not need pollination, beekeepers paid farmers for the right to put their hives on farmers’ fields, and when plants were producing little nectar but needed pollinations, farmers paid beekeepers. There was no regulation, tax, or subsidy involved” (Steelman 2004).

Summary

Externalities are side effects that come from producing or consuming a good or service. They are associated with the cause-effect chain. Including the costs of externalities to the prices of goods and services is a way forward because market failure may occur if the prices of products and services give a distorted message to the consumer. Sustainability, then, is the outcome of internalizing externalities. For example, societies could be supported toward sustainability by a global carbon tax, reflecting future externalities associated with different scenarios of human-induced climate change. A well-designed carbon pricing program motivates changes in a society. Since 1990, carbon pricing has been introduced in many national and subnational jurisdictions around the world. However, mainstreaming of a carbon price will require building political will, for example, by conscious consumers or grassroots activism (Fang 2019). Pricing through charges, levies, taxes, and permits helps “avoid leakages associated with unilateral action, voluntary restraint or technological standards on a limited set of products” (van den Bergh 2012). Overall, it seems that the holistic accountability of producers is an essential factor in solving the future challenges of citizens and societies on our finite planet. Optimal externality regulation would assure sustainable development.

Externalities (Economics)

Serpil Kahraman

Faculty of Business Administration, Department of Economics, Yasar University, Izmir, Turkey

Synonyms

External economy; Market externalities; Spillovers; Technical externalities

Definition

An externality or external economy is a microeconomic term referring to a cost or benefit when the consumption or production decisions of goods and services cause an impact on third parties which are not reflected in the market price (OECD 2019). In economic activity, producer (supply side of the economy) and consumer (demand side of the economy) are the first and second parties, while third parties refer to other economic agents or units which are indirectly affected (Economics Online 2019). The concept of externalities explains the effect of market interactions on external agents. In a free market economy, producers and consumers play a key role in a market mechanism. Any market decision may lead to misallocation of resources and/or market failure. The consumption decision and production decision directly affect the externalities which are called spillovers.

Arthur C. Pigou is one of the first economists who indicate the concept of externalities in his book *The Economics of Welfare* in 1920. Pigou noted that individual economic units consider

their interests instead of considering any externalities. Pigou used alcohol to explain the term externalities. Alcohol production leads to positive externalities for the suppliers, while the sale of alcohol leads to negative externalities to consumers (Pigou 2009).

Introduction

An externality is a cost or benefit which produces by an economic unit but effects third parties, unrelated to that unit. Externalities play a crucial role on economic growth. The effect of a market mechanism on third parties who is external called also spread effect. Externalities may be positive or negative. If the effect provides benefit to third party is known as positive externalities while the effect provides cost third party is known as negative externalities. Corporations are the key sources of externalities. Corporate social responsibility projects are examples for externalities while the air pollution as result of production is known as negative externalities.

Since the year 1930s, welfare economists began to discuss on the externalities which work through the market mechanism mainly competitive market structure. So that, in economic theory, externalities have been explained as a market failure. Thus, macroeconomic policies and interventions are applied as a regulatory solution tool to this problematic such as taxation.

Positive Externalities and Negative Externalities

An externality is indirectly related to the production or consumption (Pressbooks 2019). Almost all externalities create cost (losses) or benefit (gain). Third parties or economic agents have no control over externalities. A technical externality is another concept which indicates the cost or benefit of the externalities. Many economists focus on technical externalities as

a market failure. Furthermore, policymakers and government authorities also use this concept to evaluate the macroeconomic decision such as government intervention, regulation, taxation, etc. Finally, externalities can be either positive or negative.

Externalities are negative when the externality may increase the cost to the economy or third-party economic agents. Air pollution emitted by a factory that affects the nearby area is an example of negative externalities (Investopedia 2019). Additionally, chemicals dumped by a business organization may kill fish, animals, or plant life nearby. Here in this example, the production process of a factory is not directly related to the environment.

Externalities are positive when the externality may increase the benefit to the economy or third-party economic agents. Research and development (R&D) and similarly corporate social responsibility (CSR) projects conducted by a supply side of the economy are well-known examples of positive externalities. These projects increase benefit to the economy as well as society as a whole. Construction of a road is another example of positive externalities which opens a new residential area or increases the number of tourists, new businesses, etc. (OECD 2019).

Consumption Externalities and Production Externalities

Consumption externalities and production externalities are the two forms of positive externalities and positive externalities. Both forms of externalities may arise if the social cost/benefit is greater than the individual cost/benefit.

Consumption externalities: Negative consumption externalities (social cost) occur when the consumption of a good or service results to costs or losses to third parties. A smoker causing a second-hand smoke, who does not smoke but is affected by smoking, is an example. Positive consumption externalities (social benefit) occur when

the consumption of a good or service results to benefit or gain to third parties (Intelligent Economists 2019). As an example of this term, education not only improves personal skills but also increases the gain of society.

Production externalities: Negative production externalities (social cost) occur when the production of a good or service results to costs to third parties. Producing furniture by cutting down forests leads to negative externalities to people as well as the environment. Positive production externalities (social benefit) occur when the production of a good or service results to benefit or gain to third parties. As an example of this term, planting flowers to land makes the residential area better to look.

Market-Based Solutions to Overcome Externalities

Market-based solutions focus on market tools to reduce in which externalities are taken into account. After the 1980s, governments enacted regulations and legislations to reduce the externalities, for instance, environmental regulations and acts, direct controls, health legislations, etc.:

Taxation is another tool to overcome the issue.

Fiscal policymakers may impose higher tax rates to goods or services causing the externalities. Pigovian tax which was named by economist A. Pigou focuses on the negative externalities. This tax aims to reduce market failure that causes externalities, for instance, taxing polluters.

Subsidies are also tools to reduce the effect of externalities. Subsidies are usually in the form of monetary benefits such as tax reduction, giving grants that are given by the government authorities to supply side of the economy (Investopedia 2019).

Property Right. Establishment of property right is another solution for externalities (Economics Online 2019).

Regulation. Government authorities or policymakers may impose regulation to limit or reduce the effect of externalities.

Charities channeling donations, encouraging behaviors and moral codes, etc. are other forms of private solutions against externality.

Providing more information to economic decision-making units to increase awareness.

Summary

Externalities effect both economic growth and development. These concepts are helpful to understand the growth differences among countries. Externalities may appear as positive externalities or negative externalities. Moreover, while positive externalities are benefit, negative externalities are cost of an economic activity. Well known example is environmental pollutions as a result of production process.

Definition

Around midnight on May 24, 1989, the oil tanker Exxon Valdez grounded on the pristine Alaskan coasts. Such an environmental disaster resulted in more than 10 million gallons of oil being spilled into the waters of Prince William Sound, affecting a natural habitat that had remained virtually intact up to that date. This entry dissects its main causes

and the subsequent consequences for the global ecosystem.

Introduction

The modern concept of sustainability management requires total concern with a series of moral-ethical principles in which all members of society are committed to self-sustainable economic development (Stead and Stead 1992), promoting initiatives and measures aimed, among other aspects, to prevent future environmental crises or disasters. In addition to creating a cleaner and more environmentally responsible planet, the aim is to prevent the recurrence of environmental catastrophes of the magnitude of the Exxon Valdez disaster, whose severity would be a turning point in the field of sustainability management. In fact, it served as a sad example of what can happen anywhere and anytime, if the right measures are not taken beforehand. It should be borne in mind that until not so long ago there were territories that were still inaccessible to human beings that shielded multiple species of plants and animals. In these habitats, the lack of human interference allowed a continuous regeneration and revitalization of the biosphere, guaranteeing the survival of a good number of living beings that proliferated in an environment conducive to their existence. At the same time, the inaccessibility of these areas made them traditionally excluded from the main commercial circuits or that their natural resources were massively exploited, coexisting with native human communities that to survive were limited to carrying out entirely sustainable practices, in harmony with the environment. Alaska, “The last frontier,” was probably, if not the last, one of these last natural sanctuaries, until the fateful grounding of the Exxon Valdez.

The history of human progress is linked to the history of navigation. Names of famous vessels such as Endeavour, Golden Hind, Mayflower, Santa Maria, or Victory evoke key events in the history of mankind. Scientific knowledge, culture, and commerce spread across the seas but also

plagues such as slavery, epidemics, and countless wars and unequal conquests. In the case of the Exxon Valdez disaster, it was originally just another mega oil tanker that often plied the crystalline waters of the Alaskan Gulf on its way to its terminal at Valdez, the Trans-Alaska Pipeline terminus. But in 1989, this ship eventually generated the largest oil spill in history, precisely in a huge, virgin environment that, until then, had remained untouched by the effects of global pollution. This event must be historically contextualized based on how Alaska entered late in the world geopolitical scene, passing through the hands of various nations that began to be interested in it because of its vast natural resources. The East Coast of North America has always been the “dark side” of the New World for the European colonizers. Despite its name, the Pacific Ocean has by far the highest level of winds, streams, and storms of all the seas. On the other hand, it was not yet known exactly the abundance of natural resources of this area of the planet to attract the attention of the world powers of the time. The Spanish Crown was the first to make an appearance in those latitudes; however, its possession was more nominal than effective, hence the few settlements that were founded in this area (e.g., San Blas).

Towards the first half of the seventeenth century, the successive Russian expeditions of S. Dezhnev, V. Bering, or A. Chirikov turned the northernmost corner of North America into a clear expansionist objective until this nation made the unclaimed territory its own with the foundation of a temporary settlement in the current Kodiak Island (Three Saints Bay), later transferred to the place that today constitutes modern Kodiak (Pavlovskaya Gavan 1792). Based on the papal bull *Inter caetera* (1493) and the Treaty of Tordesillas (1494), the Spanish Crown tried to assert its acquired rights over the area, by dispatching several expeditions that founded, among others, the current Valdez (Puerto de Valdés 1790) and Cordova (Puerto Córdoba 1790). Finally, Spain desisted from further colonization of those territories to become stronger in the Upper California, where it began to create settlements such as San Diego (1769), Monterey (1770), or San Francisco (1776). Curiously, the origin of the foundation of

the current Californian macro conurbations was a collateral effect of that period, being practically any tiny Alaskan port older than the current San Francisco (Ritter 2020). In honor of the future king of the United Kingdom, J. Cook’s expedition named the sound around the villages of Cordova and Valdez as Prince William Sound (1778), one of the gateways to Alaska from the south, where the grounding of the Exxon Valdez occurred during the night of March 24, 1989.

The Grounding of the Oil Tanker Exxon Valdez

Navigation along the coasts of Prince William Sound counts with three natural enemies: the sudden storms that depend on the changeable meteorology of the area, the frequent icebergs, and the Bligh Island Reef. Thus, upon leaving the terminal, Exxon Valdez’s controls used the automatic pilot to accelerate the journey, but fearing the threat of icebergs, they had to revert to the non-automatic sailing mode. This maneuver eventually led the ship straight to its doom, running onto the reef. As in so many other environmental catastrophes, it can be determined that the tragedy could have been avoided and that the human factor was the culprit once again. As it was later proved, the maneuver carried out by the vessel was completely illogical and inopportune, and it was even rumored that some of its crew members were drunk during the navigation (Ott 2008; Leacock 2009). Other voices such as Egan (1989) are even more severe, pointing out that the command crew operated under the effects of three harmful elements: “Drinking, Fatigue, and Complacency.” This lack of professionalism was inconceivable given that Exxon, the owner of the ship, had extensive experience in the industry and that it was one of a considerable number of oil companies with interests in the area, including ARCO, British Petroleum, Union, Mobil, Phillips, Amerada-Hess, or Home oil (Hameedi 1988). None of these companies had ever observed such a reckless maneuver to leave port, the crude oil being was carried without any notable incidence over time (Morris and Loughlin 2013), but

in the case of the Exxon Valdez, it seems that arrogance also turned out to be another important contributing factor. In this way, the captain of the vessel J. J. Hazelwood warned of the disaster at 12:26 am. (Adasiak et al. 1990): “We’ve fetched up!, ah!, hard aground!, north of Goose Island, off Bligh Reef and, ah!, evidently leaking some oil and we’re gonna be here for a while and, ah!, if you want, ah!, so you’re notified.” Figure 1 provides an approximate image of the Exxon Valdez grounding area.

Consequences of the Oil Spills

Once stranded in Prince William Sound, 11 million gallons of oil were released along the Eastern Gulf of Alaska, spanning about 1100 km of coastline (Loughlin 2013). In the early days of the event, the spill extended more than 900 km from the point where the disaster began (60.8400°N 146.8625°W), impacting several protected wilderness areas such as Aniakchak National Monument and Preserve; Chugach National Forest; Katmai National Park and Preserve; Kenai Fjords National Park; and Kodiak, Alaska Maritime, and Alaska Peninsula/Becharof National Wildlife Refuges (Hofman 2013). Figure 2 exhibits a quantitative comparison of the oil spilled as a result of the grounding in equivalent terms (barrels, gallons, and liters), showing the before and after of the disaster. It should be noted that since the oil was spread over an estimated area of 26,000 km² or almost 20% of the intricate Prince William Sound coastline was affected, the first phase of the massive cleanup (1989) was extremely complicated, hence the Alaska Office of Technology Assessment deemed that only about 3–4% of the oil spilled could be recuperated (Morris and Loughlin 2013).

Following the disaster, a triennial NRDA (Natural Resource Damage Assessment) was implemented (NOS 2021), whereby this ambitious project attempted to restore the degradation of the coastal habitat between 1989 and 1992, with particular emphasis on the regeneration of the wildlife, especially, birds (Wiens et al. 2004), fishes (Short et al. 2003), crustaceans (Armstrong

et al. 1995), mollusks (Fukuyama and Hoff 2000), and marine and terrestrial (Loughlin 2013). Among the extended list of endemic species that have been most affected may be listed, among others, the pink salmon (Murphy et al. 1998), the otters (Dean et al. 2002), the seals (Hoover-Miller et al. 2001), the brown bear (Sellers and Miller 1999), the orca whales (Matkin et al. 2008), the harlequin duck (Harwell et al. 2012), the cormorant (Lance et al. 2001), or the bald eagle (Bowman et al. 1997).

Summary

Alaska’s destiny could be compared to that of a beautiful and rich lady, who lives far away from the rest, and who from time to time is pursued by some unexpected tragedy. In the course of its history, three key events can be distinguished that would definitely lead to the depletion of its natural resources from the native populations and to the progressive degradation of its ecosystem: The Russian colonization of the seventeenth century, which would cause the indiscriminate hunting and the semi-slavery of the aborigines who were literally massacred. An example of this period is the Awa’uq Massacre (1784), at the same time that sailors exterminated the Steller’s sea cow (*Hydrodamalis gigas*). The second period to take into account was the Klondike Gold Rush (1899), an event that meant the construction of several railroad lines in areas previously unknown to most westerners, with the subsequent deforestation, erosion, and overharvesting of renewable resources (Periferakis 2019). The last episode was the discovery of the Prudhoe Bay oil wells in 1968, the largest oil reserve in the United States, and one of the largest in the world. In fact, the Exxon Valdez tragedy began here, since the construction of the Trans-Alaska Pipeline System, which begins precisely in this area, required the entire peninsula to be zig-zagged from North to South by a pipeline network that has had more than 500 spill oils since its opening. Evidently, the damage caused to the boreal, terrestrial, and marine fauna at first seemed irreparable because it meant a total breakdown of the native

environment, but it has been recovering progressively after a conscientious supervision of the macro oil tankers that dock in Valdez. Much less

has been pointed out about the repercussions of the Exxon Valdez disaster among the human beings. To begin with, the damage caused to the

Exxon Valdez, Fig. 2 Volume of Exxon Valdez oil spill. (Source: Own elaboration)

natural environment resulted in the drastic alteration of the livelihoods of local populations, mainly fishing (Picou et al. 1992) and, to a lesser extent, tourism. With respect to the former, this activity has been revitalized but has not yet reached pre-Exxon Valdez levels. In relation to touristic initiatives, sustainable tourism has begun to bear fruit among visitors who are aware that the only way to preserve the environment is from a sustainable perspective (Coddington 2015).

It should be noted that the emotional impact among the civil society of the area was really devastating (Gill et al. 2012, 2016), since in a matter of hours, many of them lost their way of life, observing how the idyllic environment in which they were living seemed to be lost forever. Consequently, part of the population experienced problems of depressive-traumatic symptoms, especially the natives of the area (Miraglia 2002), who once again saw how the greed of Westerners was damaging their ancestral land (Palinkas et al. 1993). In spite of the progress achieved, it is clear that the entire area has not yet been regenerated and, much less, the

environment has not been returned to its original state but at least it is worth celebrating the commitment to the regeneration of nature itself based on its own sustainability, giving an opportunity to new cutting-edge techniques based on bioremediation (Atlas and Bragg 2009).

The implications of the Exxon Valdez disaster with the area of sustainability management are quite evident given its worldwide repercussions, both as an unprecedented environmental catastrophe and for Exxon, the shipowner, which had to face several billion-dollar lawsuits due to the damage caused to the Alaskan coastline. Harrald et al. (1990) argue that the tragedy provided extra motivation for corporations to combat environmental pollution and to establish contingency plans in turbulent environments in which the risks assumed by each firm are disclosed to policymakers and public opinion. Similarly, Harrald et al. (1992) point out that the disaster represented a redefinition of public and private organizational structures aimed at redesigning the business responsibility to handle the magnitude of these types of events. In short, the disaster implied an organizational improvement based on

three points: the anticipation of emerging phenomena that the business might face, cooperation with each stakeholder, and the establishment of a high-performance decision-making unity. It should be remarked that after the vessel was repaired in July 1990, it sailed again a few months later under multiple denominations (Dong Fang Ocean, Exxon Mediterranean, SeaRiver Mediterranean, S/R Mediterranean, Mediterranean, and Oriental Nicety). However, the devastation left by its grounding along the coast of Alaska will take considerably more time to be reversed.

Definition

Fairtrade is a term which has two distinct concepts. First, it is an institutional arrangement between producers in developing countries, and supply chain participants and ultimate consumers aimed to improve the working conditions and increase the revenues of producers. It provides an alternative to free trade which considers international trade as simply a buyer looking to purchase a product at the cheapest price possible. Rather, fair trade considers the impact of production on local population and the unfairness that can result from power imbalances between wealthy developed world purchasers looking to buy in bulk on the spot market and poorer, developing world producers who do not have the means to even out fluctuations or options to rapidly change livelihoods in response to market conditions. Fairtrade changes the way trade works through changing market institutions to provide better prices, decent working conditions, and a better deal for producers in developing countries (Nicholls, 2010). The second use of the term fair trade is as the name of an organization, Fairtrade Labelling Organizations International e.V., known commonly as “Fairtrade International” (“Fairtrade”) – an organization that implements a fair trade trading system.

Nature of Fairtrade

Fairtrade aims to enable producers to receive a larger share and a more stable market for their products with the result that they are able to better their lives and control their future. It aims to challenge businesses and governments by connecting consumers more closely with producers who make their products (Nicholls, 2010). Such trade focuses on conducting trade on the basis of concerns beyond mere finance. It aims to bring into the equation such matters such as environmental conditions, human rights, and labor laws.

Fairtrade benefits small-scale businesses in communities with limited social and economic resources, and it creates opportunities for community improvement. It is operationalized by small businesses and the communities (Nicholls, 2010). It can be described as a trading system developed collaboratively between parties in the developed and developing worlds, based on notions of equality and dignity, the main aim of which is to improve equity in international trade. It stands as an alternative to the international free trade system which views trade in purely financial terms, as a transaction in competitive global markets.

Fairtrade aims to offer producers in the developing world better trading conditions in terms of net proceeds and stability, as well as securing the rights of marginalised groups, better wages, standardised working conditions and protecting children (Gendron et al., 2009).

In essence, fair trade connects producers more directly to consumers. It provides consumers with information about and means to address the needs for social justice experienced by producers in the developing world. Consumer support for these social justice initiatives enables not only developing world producers to have better livelihoods but also Fairtrade organizations to advocate for broader reforms of the international trading system to improve matters of justice on a larger scale. It allows people to buy products that align with their values and principles (Watson, 2007).

As an organization, Fairtrade is a producer-driven initiative, which, although centrally coordinated, provides producers with a strong voice at

every level of the organization – from how it invests to operations of local organizations to voice in Fairtrade's global decision-making processes (Nicholls, 2010). Fairtrade businesses work hand in hand with the marginalized groups, hence ensuring that favorable conditions in terms of working conditions and environmental factors are met (Renard, 2003). The benefits of fair trade extend broadly to the community and include improved education, healthcare, and environmental sustainability (Le Mare, 2008).

Ethical and Economic Foundations

Ethically, fair trade rests on a foundational argument that the production process is a process with ethical characteristics – from treatment of employees, women, and children to community impacts and environmental sustainability impacts. Further, it acknowledges that economic transactions are not necessarily fair. Economic transactions can reflect power differentials and information asymmetries which can be exploited. The lack of commensurability both in terms of products and producer options—i.e. the limited choices producers and vendors in developing countries have—can tip the balance excessively in favour of more powerful buyers in the developed world.

The implications of the recognition of these issues are wide-reaching. It implies that consumers need to be aware of the methods and costs of production and not only price or physical qualities of products and services they consume. Consumers ought to be aware of and be concerned about the ethics of the processes by which goods and services are created and distributed (Hira & Ferrie, 2006). Further, the recognition creates a moral ought or call to action, in terms of purchasing decisions with respect to products. It implies a consumer choice to support exploitative practices in international trade and consumption of commodities produced in unfair conditions or to support fairness more broadly.

Fairtrade can be distinguished from apparently similar movements that challenge conventional methods of production. For example, the organic

food movement, which proposes that conventional production processes are undesirable, offers an alternative product which is argued to be an inherently better product (free of pesticides). By way of contrast, fair trade products have the same physical characteristics as other competitive goods. For example, a fair trade chocolate bar may have precisely the same amounts of cocoa, sugar, and fat as a non-fair trade chocolate bar (Hira & Ferrie, 2006). Rather, the difference is in the processes of production and trade. These processes imbue the product with a different ethical quality, a set of values that have a particular worth to the consumer.

Economically, fair trade was driven in part as a response to the free trade movement which swept across the world in the 1980s following shifts in monetary policies associated with Reagan in the USA and Thatcher in the UK. Free trade at a theoretical level is considered fair because the parties are free to determine what is a fair price for their goods. They are deemed to be willing to buy and sell only for a price that they believe is fair to them. There are many problems with this model, including massive public subsidies to some parties and unequal bargaining power between buyer and seller.

The obvious unfairness of free trade in agricultural products came to public attention as a result of publicity work by NGOs. For example, massive agricultural subsidies granted to developed world producers, exacerbating the poverty and poor work conditions in the developing world, became common knowledge through campaigns such as Oxfam's "Make Trade Fair" (Aaronson & Zimmerman, 2006). In such difficult circumstances, further harm and exploitation may well result as people become more desperate to survive.

Historical Foundations

The fair trade movement traces its beginnings back to popular concerns for social justice and a sense that free trade agreements were not serving either producer or consumer interests. These social justice concerns included concerns about the failure to address extreme poverty despite

increased trade and increased levels of wealth gaps between the rich and poor (Hira & Ferrie, 2006). The Fairtrade organization began as a small movement which, by many accounts, started more than 30 years ago by the launch of a Max Havelaar brand of coffee in the Netherlands. The core idea was that trade could be founded upon something other than pure economic norms, that is, on ethical principles (Hira & Ferrie, 2006). The Fairtrade founders argued that such conducting trade on nonmarket norms required little additional effort or cost and provided significant benefit to developing world producers. Further, they argued that fair trade demonstrates a wider conceptualization and greater impact resulting from developing world producer determinations of development and a significant step away from developed world ideas and practices such as foreign aid and related finance-focused initiatives (Watkins & Fowler, 2002; Hira & Ferrie, 2006).

There are two main versions of fair trade. The first version focuses on the exploitative nature of global capitalism particularly in international trade and aims to create a new alternative system based on new institutions. This alternative set of market institutions is used for fair trade products. It operates through a different set of norm makers, distribution channels such as NGOs (nongovernmental organizations), or "alternative trading organizations" (ATOs). The second version, one supported by Oxfam, is more experimental, trying new ways to promote more equitable trade by using existing trade institutions, including commercial retailers (Hira & Ferrie, 2006). The second, less radical version of fair trade looks to integrate CSR policies into supply chains from primary industry producers to retailers.

Fairtrade System: Fairtrade International and Certifications

Fairtrade International operates by developing standards which are then disseminated from primary producer to retailer. The standards are product specific rather than for the whole of an organization. It provides advice and support to

help producers comply with standards and so participate in the Fairtrade trading system by receiving the well-known green and blue swirls on black background logo. That logo is properly referred to as the Fairtrade Labelling Organizations International (FLO) certification mark.

Over the past 20 years, sales of fair trade goods – particularly those labeled with an FLO certification – have grown exponentially. Fairtrade International leads the independent global movement for trade justice, and as a branded organization, it is the most widely recognized fair trading standard in many leading markets (Anderson et al., 2014).

Fairtrade offers four important benefits for producers. These, as identified by Ronchi, are “(1) *stable prices* that cover the costs of sustainable production; (2) *market access* that enables buyers to trade with producers who would otherwise be excluded from market; (3) *partnership* (producers are involved in decisions that affect their future) and (4) *empowerment of farmers and workers* (assistance for producer organisations to understand more about market conditions and trends and to develop knowledge, skills and resources to exert more control and influence over their lives)” (Ronchi, 2002).

Fairtrade places obligations and restrictions on producers. For example, to be truly fair, producers are required to pay minimum wage, to adopt and ensure safe working conditions, and to contribute to environmentally sustainable practices. Similarly, it constrains buyers. For example, fairtrade sets a minimum price to provide a floor for prices. Having a floor, allows farmers to invest in complying with fairtrade obligations and continue to operate in adverse conditions such as when their particular commodity is flooding a global market. Normally, this event would and drive prices down below the floor price (Parrish et al., 2005).

Critics of Fairtrade

The fair trade economic model has limitations that generate criticism (Reed, 2009). Fairtrade organizations, for example, are criticized for working with companies that have track records of

unethical behavior or are currently engaged in unfair practices in their international trade (Reed, 2009). These concerns are real and need to be considered carefully. Companies that have suffered reputational harm may change executive leadership which may in turn cause them to change course. Of course, the possibility remains that there will be no change of course but merely an effort to use Fairtrade as a shield; however, that is less likely given the thoroughness of the standard and the important point of Fairtrade International's policy of certifying products but not companies.

The fair trade economic model also faces challenges. Some critics argue that it contains an inherent structural contradiction: if the minimum price for fair trade products is too high, the low level of sales will make the product unviable and unable to deliver on its promise of increased revenues to producers. If, however, the floor price of fair trade products is lower and competitive with non-fair trade products, while the sales volume may increase, the impact on poverty reduction will be insignificant because there is not the excess money generated to address the issue (Sylla, 2014). Thus, a problem remains on how to balance fairness with consumer demand in competitive markets.

Perhaps as Rosenthal says, “fair trade” could be more accurately described as “trade which is less unfair.” In fact, in certain instances such as those discussed above, fair trade can mean less money for a producer (Mookerjee, 2019). The engagement with Fairtrade International and compliance with the Fairtrade International standard can be expensive. In addition, if demand for fair trade products is too low, producers may not be able to sell all their products with a fair trade label, thereby forcing them to sell their products with the Fairtrade production and compliance costs but without the fair trade premium.

Summary

Fairtrade aims to resolve fairness problems between producers and consumers. It does so by way of introducing different values and systems

that reduces the unfairness common in trade related to agricultural and other primary industries.

Family business; Family entrepreneurship; Family firms

Definition

The definition of a unique concept is also challenging, as there is a diversity of definitions exposed by the different researchers (Chua et al. 1999). Family-owned businesses, in general, perform differently from non-family business, have a different capital structure, present the family as the main ties inside the management and board of directors, and use family governance to organize the expectations of the family to the company's management.

Because of that, board of directors is one of the parts of the family firm's governance structure (Miroshnychenko et al. 2021). Astrachan et al. (2002) use the variables power, experience, and culture to explain the influence of family in family-owned-business.

According to Gersick et al. (1997), family businesses are those who have family members in property and business management. Also, according to Patel and Chrisman (2014), they are a corporate type that can reconcile economic and non-economic goals. They are defined as a family ownership and control on a firm and vision for how the firm will benefit the family, potentially across generations (Chua et al. 1999; Patel and Chrisman 2014).

Some of the goals in the family firms exist as a form of longevity through investment, innovation, risk reduction, and increased sales. They use, as strategies, the observation of their resources to preserve socio-emotional characteristics and financial wealth, inherited or transmitted by beliefs and social norms that distinguish them from non-family companies. Gersick et al. (1997) to cross the boundaries of corporate and economic interests (Bornholdt 2005), and maintain the necessary balance between organizational and family interests through formal policies (Stalk and Foley 2012). Litz (2008) argues that family businesses rely on family-specific resources, and this business family seeks company support to achieve their goals.

Family organizations are that one's identified by the possession of control of partners belonging to one or more families, when family interactions and shared interests have some level of trust

(Granovetter and Granovetter 2000), sharing resources, information, and knowledge (Stewart 2003). Family control is identified in several regions and in different legal systems, in them being part of the United States, Western Europe, and East Asia (Anderson and Reeb 2003; Franks and Mayer 2001; Gadhoum et al. 2005; Lee 2006).

It is also verified that all concepts that define dynamics (Casillas et al. 2007) and specificities (Debicki et al. 2009) of family businesses circulate around the control, structure, property, and power that the family exercises, and the participation of the family in the management of the company, adjusted by the ideal of succession to the following generations. However, there are authors who disregard the obligation of the existence of control or property to define the company only by family origin (Martins et al. 1999).

Background

Family-Owned Businesses (FOB) represents one of the predominant forms of ownership and management in economic systems worldwide (Gomez-Mejia et al. 2010; Ho et al. 2020; Morck and Yeung 2003; Peng and Jiang 2010; Segura and Formigoni 2014; Yoshikawa and Rasheed 2010).

It is estimated that 70% of the global GDP is generated by family firms (Russel Reynolds Associates 2019), which provide 60% of the companies in the world and are responsible for 50% of the jobs. Family firms represent the main form of business organization in the world (La Porta et al. 2002).

According to Morck and Yeung (2003), this type of management and ownership has been important to free-market economies along the centuries, as names such as Rothschild, Medici, Ford, Thompson, and Krupp, among others are well known as family business and reflect the size and importance of the family inside the businesses.

The economic impact of family business in the firm control is substantial according to Miroshnychenko et al. (2021). It means that the

growth of family-owned business usually presents 2% more than non-family ones.

In addition to being responsible for expanding wealth, generating jobs and income because of the quantity of family firms and proportion around the world, family-owned businesses have also raised the volume of publications in recent decades (Basco-Rodrigo 2010), showing scientific relevance in this matter. However, scientific research is still evolving. To the extent that this importance is recognized, scientific interest focused on understanding these organizations is notably growing (Miroshnychenko et al. 2021) through reflective studies on the development of this field of research (Ramírez-Pasillas et al. 2021).

This interest can be noted by the intense production of articles, frameworks, and research developed by authors around the world and by frameworks and business models developed by Family Business Associations, as is the case with models developed in the United States, Europe, Asia, and Latin America. New models in family businesses and structures such as Family Firm Institute (FFI 2021) and Family Business Network (FBN 2021), among others, are designed to assist professionals who deal directly with issues related to this type of organization.

Summary

Family-Owned Businesses (FOB) represents one of the predominant forms of ownership and management in economic systems worldwide. Family businesses are those who have family members in property and business management. Also, they are a corporate type that can reconcile economic and non-economic goals. They are defined as a family ownership and control on a firm and vision for how the firm will benefit the family, potentially across generation.

Definition

Responsible finance is offering financial services in an accountable, transparent, and ethical manner. By definition, responsible finance must focus on financial service providers, (their practices, what they do or do not do) and on clients (mainly aimed at improving their capacities to access and use high quality financial services) (Yamini and Bhat 2012).

The Responsible Finance Forum (2011) defines Responsible Finance as “coordinated public and private sector interventions that encourage and assist financial service providers and their clients in improving their understanding and approaches, practices, and behaviors that can eventually contribute to creating more transparent, inclusive, and equitable financial markets.”

Responsible Finance is also linked to financial inclusion and consumer protection enabling individuals and firms to participate in and benefit from the formal financial system (The World Bank 2020).

Introduction

The need to introduce a framework for social responsibility into the world of finance has given rise to what is known as sustainable finance. This new direction expands on the analysis of economic behavior (classic financial theory) and agent psychology (behavioral finance), including their moral and social behavior, to focus on a triple-bottom line: social, environmental, and financial performance.

Financial intermediaries, particularly credit institutions, play an active role in countries' economic and social development through their capacity to select investment and consumer projects, to manage risks, and to make decisions about who can access capital and the activities to be funded. They carry a large weight of social responsibility in the fight against poverty, social inequality, and sustainable development. The finance sector is waking up to this responsibility and to the economic consequences of evading it. Its economic function is no longer limited to being a mere intermediary of capital flows and properly managing the financial risks. It must assess and manage other types of ethical, social, and environmental risks and offer products and services that contribute to a more humane development of the planet in response to the demands of consumers who are ever more concerned about how their savings are invested and shareholders taking a greater interest in the economic impact of certain types of unsustainable behavior.

Key Issues

CSR in the banking sector (as in other business sectors) has **five distinct dimensions** (Muñoz and de la Cuesta 2010):

1. Financial. Maximizing a company's profitability over the long-term, which translates into an increased value for the shareholders, thereby generating wealth and fostering job creation in society.
2. Corporate. The implementation of policies of good corporate governance and information transparency relating to all spheres of the company's business, which unquestionably stamp out corrupt practices within the organization.
3. Human Resources. Acting responsibly within the domain of human resources, nurturing the company's human capital, and pursuing diversity in staff training that will fire employees' motivation and commitment and in turn lead to greater productivity and a keener interest in their work, thus contributing to the added value of the company.
4. Environmental. Social requirement to respect the environment in which the company operates to ensure the sustainable use of the natural resources available to society.
5. Social. Investments in social projects in order to pay back to society part of the benefits the company reaps when people use its products or services.

Implementing CSR affects banking institutions in both their internal and external aspects.

- a) Internally. CSR implies transferring environmental and social responsibility to the bank's **internal management**. This requires compliance with the International Labour Organisation (ILO) conventions and with Human Rights, gender equality and other requirements related to employment matters. In relation to the environment, it necessitates a sustainable use of energy, staff training in sustainability, better recycling practices, and an improved energy performance. In the social sphere, it requires

getting involved in society through the sponsorship of cultural, educational, and welfare activities or through charity donations.

- b) Externally. Integrating CSR into the basic business of **banking intermediation** and financial market investment requires taking on board environmental and social considerations in product design, credit and investment policies and the business strategy in general, including risk assumption. These areas would include socially responsible savings products and investment funds and ethical deposit accounts. It also covers credit and investment products that assess the social and environmental impact of the activity to be financed, channeling more savings to responsible projects and innovative technologies.

Knowledge of the main social and environmental risks of the finance business is necessary to create a roadmap for implementing CSR policies in financial institutions that are looking to avoid such risks (Fernández 2014).

1. Over-indebtedness. In their quest for greater profits, financial institutions can drive levels of indebtedness above the reasonable limits, leading to detrimental economic and social consequences in the medium and long-term (inability to repay the debt, property repossession, etc.). Banking institutions are responsible for correctly assessing and managing the lenders' risks and for ensuring that the loan is used in a prudent manner, avoiding over-indebtedness.
2. Financial exclusion. The concentration of the banking sector and the ensuing branch closures can lead to growing levels of geographic financial exclusion. Access to financial services is identified as an essential factor in social cohesion, alongside basic banking services, positive discrimination for certain social groups (people with few resources, ethnic minorities, students, the disabled, rural population, etc.), and regional development, in need of capital flows.
3. Evictions. Closely linked to financial exclusion is the loss of one's home or business premises

- due to mortgage nonpayment. Banking responsibility necessarily requires adapting the products sold to the needs and capacities of the groups served, including an assessment of their financial education and the application of good banking practice, such as assets in lieu of payment, debt renegotiation, access to social rents, etc.
4. Other risks to avoid and behaviors to encourage in the financial sector:
 - a) Need for the financial inclusion of small and medium enterprises (SMEs).
 - b) Avoid the selling of hybrid products (such as preferential shares and subordinated debt) without assessing the suitability or appropriateness of the product for the client, or clients with insufficient financial knowledge.
 - c) Avoid money laundering.
 - d) Avoid trading with companies that may be involved in serious breaches of human rights. These activities may include funding, particularly of large projects (project finance), institutional investment and asset management.
 - e) Environmental impact and climate change. The direct environmental impact of banking operations has traditionally been viewed as low, even neutral, compared with the industrial sector. But banking must assume an indirect responsibility, through the projects it finances, which often have a significant environmental impact.
- Implementation of totally transparent lending policies in Developing Countries.
 - Codes of Conduct: disclosure of policies that will have a clear impact on various business areas so that clients and suppliers are aware of the standards under which they will be judged.
 - Adoption of social inclusion policies to improve access to banking services for groups in society who may be excluded due to a variety of reasons.
 - Information system that encompasses social, environmental and corporate governance factors, whose main indicators are reflected in a sustainability report previously verified by an independent agency.

Future Directions

The UN estimates the gap in financing to achieve the Sustainable Development Goals (SDGs) to be \$2.5 trillion per year in developing countries alone (UNCTAD 2014). SDGs were adopted on 25 September 2015 by 193 countries and focus on ending poverty, protecting the planet and ensuring prosperity for all as part of a new sustainable development agenda. A total of 17 goals and 169 targets have been set, to be achieved by 2030.

Therefore, responsible finance has a key role to play in achieving Sustainable Development Goals by financing the gap and promoting investment products that help to achieve the goals.

Fiscal Fairness

[Ethics of taxation](#); [Tax fairness](#)

Definition

Fiscal ethics is the normative analysis of the fiscal rights and duties of citizens and residents (taxpayers), viz., the distribution of the fiscal burden across a given population. This burden includes taxes but also deductions and exemptions. Fiscal ethics is concerned with the justifications of specific tax architectures, i.e., how to render a system fair (fiscal fairness). It is the first step toward a full-fledged theory of justice.

However, while distributive justice focuses on principles that should guide the repartition of resources collected through, fiscal ethics deals with the principles that should apply to such collection. Efficiency, equality, individual responsibility, merit, and other principles can be used to determine and modulate the tax burden, as they can justify the distribution of resources. While crucial, the topic has attracted little attention among ethical theorists. One of the reasons is that taxation is perceived as being only instrumental to redistribution. Therefore, the ethical qualities of a tax system would be a strict function of the redistributive performance of such a system and how it enables specific, valued, redistributive schemes. However, one may argue that taxation contains intrinsic ethical dimensions in relation to the core justifications of taxation (why taxing?); the choice of a tax base, e.g., income, wealth, or consumption (what to tax?); and the manner taxation is undertaken (how taxing?).

Introduction

Taxation is key for modern states. It generates the resources necessary for providing public goods and services as well as for funding poverty alleviation, social safety net, and redistribution. Taxation is sometimes judged to be valuable beyond the goods, services, and other material advantages it permits financing. For instance, it would promote human development or the civilizing process. As written in the Journal of the House of Representatives of the State of Vermont (October Session, 1851): “Taxation is the price which we pay for civilization, for our social, civil and political institutions, for the security of life and property, and without which, we must resort to the law of force.”

In spite of its importance for industrialized countries, taxation is a largely disregarded topic in ethical and political theory, with few exceptions (e.g., Gaisbauer et al. 2015; Murphy and Nagel 2002). The main reason is that redistribution, namely, what to do once monetary resources have been collected, is perceived as the crux of the matter, the collection being simply

instrumental. Put differently, taxation would be morally neutral, its value being derived from the manner resources are redistributed.

Fiscal ethics fill this lacuna by covering the following issues:

1. *Why taxing at all*, i.e., what could justify that public institutions collect part of individuals and organizations' resources? Put differently, why having taxes instead of something else, such as voluntary contributions, or nothing?
2. *What taxing*, i.e., which is/are the right tax base(s), i.e., income, consumption, or wealth, and for which reasons?
3. *How taxing*, i.e., which rates to impose in a flat or progressive system (with which brackets)? With which specific rules, e.g., allowances, exemptions, etc.?

Fiscal ethics is central in democracy, especially for states with ambitious social programs and substantial responsibilities for providing public goods and services, such as welfare states. Arguably, the manner that specific schemes are designed as well as the arguments used for supporting them are important for tax acceptance, i.e., how taxpayers tolerate the fiscal burden.

A common misconception is to confound taxpayers and citizens. However legal residents are also taxed, e.g., on their income or value-added tax (VAT), and illegal ones do not escape all their fiscal duties. Even if the latter are part of the shadow economy through non-declared jobs, they still pay tax on their daily expenses, for instance, the VAT. In addition, not only physical persons are taxed; juridical persons are too (e.g., corporate tax) even if different conditions and tax rates may apply.

Fiscal ethics covers several kinds of issues.

Why Taxing

The first relates to why leveling taxation at all (instead of, for instance, relying on voluntary contributions or private purchases) for paying for public goods, services, social protection, insurance programs, redistribution, and so forth. Various, non-mutually exclusive, reasons could justify why taxing.

One justification is grounded in efficiency. Paid taxes are individual and organization contributions to the purchase of collective goods and services, which economists define as "public goods" (Samuelson 1954). The argument describes members of political communities as pooling their resources for buying goods and services such as national defense, schools, hospitals, roads, bridges, etc. (Davis 1998). Taxes are then the "bills" sent to each potential user of these services.

Insurance programs are a prominent kind of public services. The main programs – national healthcare, unemployment benefits, and public pensions – use a sizeable portion of the welfare states' budget. In that context, taxes can be equated to premiums paid for being eligible to insurance provided (or simply funded) by the state (or by public agencies).

Contributions to public insurance significantly diverge from premiums paid to private companies because they usually do not follow a strict actuarial logic, i.e., they do not strictly reflect one's risk exposure. For instance, smokers do not pay more than non-smokers for having their medical services and drugs covered by public healthcare. Moreover, contributions are usually bundled with other taxes, making the relation between premiums and risk exposure looser. Finally, since such contributions are bundled with other taxes (e.g., on income), they tend to reflect one's ability to pay. Individuals and organizations contribute proportionally to their financial capacity, i.e., income or wealth.

The public goods and services argument is rooted in efficiency. The state is justified to tax the potential beneficiaries of public goods and services, i.e., citizens and residents, due to higher efficiency than private actors for providing or paying for these goods and services. Since goods and services, such as national defense, are non-rival and non-excludable, i.e., individuals cannot be barred from enjoying them and their level of consumption does not, theoretically at least, reduce the amount available to other individuals, it creates a risk of free riding, i.e., individuals not contributing, which the state is better equipped than markets to handle, due to its power of constraint.

The efficiency argument applies to public insurance too. States are more efficient than private actors and markets at providing public insurance, i.e., protection against risks, because they have substantially more resources than most private actors for fulfilling their obligations, because by insuring the whole population, risks can be more precisely calculated (so-called *Law of Large Numbers*; the larger a sample is, the more the risk distribution can be calculated while being stable), because states can monitor more closely their population and impose some preventive measures (for reducing adverse selection and moral hazard) and can commit future generations (Moss 2002).

A second justification for taxation consists in underlining the advantages of being part of a political community. Those advantages go beyond public goods and services. They encompass stability and social cooperation. Put differently, individuals and organizations *directly* benefit from being included in a political community through public goods and services but also *indirectly*, through the quality of interpersonal relations and social networks sustained or rendered possible by public institutions. In other words, through taxation individuals pay for the advantages they receive living in a steady and pacified society that is conducive to strong cooperation and high-quality social capital.

A third justification relies on equality. One might claim that states should guarantee to their residents some basic level of material equality as a matter of respect or for strategic reasons, such as avoiding the disruptive effect of too large inequalities. Furthermore, since democratic states are assumed to express popular will, redistribution and taxation could be interpreted as manifestations of what individuals and organizations (consider they) owe to each other.

In any case, the argument posits that taxes are instrumental for redistribution (by simply collecting resources), or redistributive in themselves (by modulating the contributions based on, for instance, the ability to pay or wealth). Nonetheless, taxation is not a neutral instrument. It conveys its own norms, independently of how resources are used, how they are collected express

different political priorities, views on fair social cooperation and carry different outcomes. For instance, it is not equivalent to finance public spending by a progressive wealth tax, VAT, or a flat income tax.

Finally, taxes could be seen as vehicles for inclusion. By paying taxes, citizens and residents actually manifest their commitment to the political community. Vice versa, by imposing specific taxes on residents, public institutions spell out the conditions for inclusion. In other words, taxing has an expressive value. It enacts individuals and organizations' political membership.

Other reasons could justify the very existence of taxes. Nonetheless the key idea is that taxes are more than instruments for redistribution. They have a longer reach and various ethical implications.

Tax Bases

The second issue is encapsulated in the question: *what taxing*, i.e., which tax base (income, consumption, wealth, or something else) to choose or how to distribute the fiscal burden over different bases? Each base generates specific supporting reasons, objections, and so forth.

Although this justificatory dimension is central for fiscal ethics, the issue is less visible for public policy. The reason is that states levy taxes on several or all bases, the only difference being how the whole tax burden is spread across the different bases. Nonetheless, the issue of what taxing is conceptually important, and such a choice (or the repartition of the tax load between the different bases) has ethical underpinnings and political consequences (e.g., in terms of tax acceptance).

Ethical underpinnings are noticeable in the common pool allegory (Hobbes 1996). The pool symbolizes the resources of a society that people augment by their work or reduce through consumption. The allegory usually serves to tackle income tax, which equates taxing entities according to their contribution to the pool. The apparent unfairness of such a tax is sometimes used to advocate for choosing other bases (or changing the distribution of the tax load across the various bases). One of such propositions is to

tax spending (or consumption), i.e., individuals' use of the pool rather than their contribution to it (Kaldor 1955). This illustrates the ethical dimensions embodied in fiscal issues.

The choice of a tax base manifests what taxpayers (think they) owe to each other. This aspect is, however, obscured by the libertarian view according to which taxes are about the state (illegitimately) seizing individuals' resources. This view opposes the state and taxpayers, downplaying a crucial point. Taxation cannot be reduced to confiscation. Along with law, it also articulates the (mutual) duties of members of a given society. Fiscal ethics is about revealing, discussing, and ironing out such duties.

Returning to the common pool allegory, the three main tax bases are income, spending (consumption), and wealth.

Income Tax

Income tax is an umbrella denomination. Although it is typically understood as referring to tax levied on earned income, i.e., gained from labor-like salaries, it covers all sorts of income, such as land income, return on capital, loan interest, and so forth. States usually levy taxes on income no matter the origin, but they impose different rates depending on the kind of income. The most discussed form is the tax on earned income.

Taxing income is claimed to offer several advantages. First, it is quite transparent and straightforward, since people are usually aware of how much they earn. Second, it is easy to implement, especially in a withholding (or retention) system where income payers collect the tax. Third, it can appear fair to tax people in proportion to their ability to pay. It mirrors the intuition that is fair that contributions to the provision of public goods and services are adjusted, to some extent, to one's financial capacity. Furthermore, public institutions could be considered as having a duty to promote some level (to be defined) of material equality. Income tax could then help to fulfill this duty depending on how it is implemented, e.g., progressivity.

Objections against taxing (too heavily) income usually rely on one of these two arguments: the

right to one's own labor (figured by income) and the tax's disincentive or deterrent effect.

The first argument is grounded on the idea that *individuals are entitled to the fruit of their labor* represented by income. The argument could be traced back to John Locke (1988), who claims that individuals have a right of property on their body and on the value created by their work as long as enough of the common resources is left to others (so-called Lockean Proviso). In short, individuals are entitled to their income and so do not deserve to be deprived of it.

There is little controversy about the fact that individuals have a prima facie right of appropriation on the fruits of their labor. This does not, however, imply that such a right is absolute and applies to the totality of their income. It could be argued that individuals' income partly results from using public goods and services, for which an income tax compensates. It could also be claimed that individuals, for earning their income, rely on the work of other individuals, which contribution is only partially reflected by the wages paid to them.

Hence, the issue is *how much of their income do individuals deserve or merit?* One could claim that rights are independent from merit or desert in the sense that they are unconditional by nature. Individuals should enjoy their rights independently of what their acts. However, this argument is not clear-cut. Some basic rights (e.g., freedom of movement) might be restricted due to perceived (lack of) merit, which is the case for incarcerated criminals. Therefore, to some extent, it makes sense to coin the issue of entitlement in terms of merit or desert.

In any case, the debate is not so much whether individuals are entitled to anything, but rather to *how much*. Few authors, mainly libertarians, deny the legitimacy of the state to provide public goods and services and consequently tackle the legitimacy of taxation. Conversely, fewer argue that individuals are entitled to nothing. So, the ethical discussion happens between these two extremes, captured by the *how much* interrogation.

The second kind of objection raises the risk of a disincentive or deterrent effect. In case of

excessive taxation, taxpayers may either work less (reducing the general prosperity and tax revenues) or slide into the shadow economy (reducing tax revenues). The argument relies on the empirical assumption of individuals being significantly responsive to material rewards (money) when deciding how much to work or whether to declare their activities.

As for the previous objection, the relevant debate is centered around *how much*: how much tax pressure leads individuals to reduce their work *in a proportion that is actually harmful* or to enter the shadow economy? In other words, common objections do not forcibly undermine the principle of taxing income but raises the issue of what an efficient level could be. The discussion calls for empirical evidence provided by studies investigating the reaction of a given population to various tax levels.

Spending Tax

The second tax base is spending or consumption. Such taxes can be indirect (e.g., sales tax or value-added tax), i.e., paid out of the goods or services being consumed, or direct (e.g., expenditure tax), i.e., paid out of the whole consumption of an entity. The main justification for such taxes is that individuals and organizations should pay taxes proportionally to their use of resources (the famous “common pool”). The case for a spending tax is strengthened by growing concerns about the preservation of natural resources, reduction of energy consumption, and decrease of the carbon footprint.

The basic justification for indirect spending taxes is the ease of implementation, explaining why many countries have adopted them. There are usually few brackets (different rates), sometimes only a flat rate and collection is assumed by sellers. Another advantage is that such taxes are immediately responsive to surges of the economic activity. When the economy expands, spending rises mechanically, which leads to an increase in tax collection. This reactivity could turn into a disadvantage during crises since the contraction of tax collection will closely mirror the economic downturn.

The main objection against indirect taxes such as VAT is their regressive nature. They burden

proportionally more modest individuals than wealthier due to the higher propensity to consume of the former. For instance, sin taxes on alcohol, tobacco, snacks, fat food, or soft drinks are known to strain more modest budgets. Indirect taxes cannot be modulated according to one’s resources; they apply to anyone at the same rate, which strengthens the concerns about their regressive nature.

The fundamental justification for direct taxes such as an expenditure tax lies in the flexibility they offer in comparison to indirect taxes. The latter are easy to implement but at the same time they are usually insensitive to one’s income or wealth, and, therefore, are regressive. The main comparative advantage of a spending tax is that it applies to one’s whole volume of consumption and can be modulated according to one’s use of collective resources.

Some authors advocate for consumption (or spending) tax in order to tame excessive or conspicuous consumption (Frank 1999). The argument is that individuals use consumption for signaling their relative standing. Therefore, social patterns of consumption are deeply affected by individual willingness to appear cool, successful, etc. This implies that part of consumption, and the strain imposed on collective (natural and produced) resources, is not determined by absolute needs but by relative considerations, interpersonal comparisons, and the desire of social recognition.

The problem is that individuals tend to consume more than required for fulfilling their needs. This excessive consumption is claimed not to bring lasting satisfaction, because it applies on positional goods (goods which bring satisfaction relatively to their social scarcity, i.e., how restricted their access is). Moreover, the more individuals consume (especially positional goods), the more they raise the collective standards of appropriate spending, the more everyone feels pressured to increase their expenditures for not falling behind, preserving access to specific social groups or networks, and so forth.

In that context, and assuming that the evaluation of the situation is correct, a spending tax with an incremental rate (cf. below) is sometimes advanced as a possible solution (among others

such as scaling down commercial advertisements). The idea is to tax people on their spending with escalating marginal rates, i.e., that higher amounts of consumption will be taxed at a proportional higher rate. The justification is that people should pay more in proportion of their spending, the rising pressure they impose on common resources, and on their peers for spending more.

Such a proposition attracts criticisms on both the very principle of such a tax and the incremental design. The main criticism is derived from the ownership argument above. It is to say that individuals are entitled to their income (and ensuing wealth) and, therefore, entitled to use it as they please. Again, few deny that individuals and entities have a *prima facie* right to decide for themselves how to use their income or wealth, but it does not follow that such a right cannot be constrained. For instance, individuals and entities cannot, everything else being equal, use their resources for harming someone else.

By arguing that excessive consumption creates social costs which are, to some extent, unescapable (also labeled as positional externalities [Frank 2008]), incremental consumption tax seems to be justified in terms of the harm principle (Mill 1859), i.e., that public institutions are legitimate to interfere with private decisions if it harms other individuals. The strength of the argument correlates with the extent of excessive consumption. If such consumption turns out to be marginal or insignificant, the justification for taxing consumption at an incremental rate loses most of its force.

Wealth Tax

The last tax base is wealth. While income reflects a flux at a given moment, wealth represents a stock that is the result of past fluxes. Wealth thus provides a more accurate image of one's ability to pay at a given moment of time. Moreover, it offers a superior tax base than income for fulfilling state's egalitarian duties since income is simply one of the sources of wealth and what matters is what taxpayers' net worth (which income does not capture).

In addition to egalitarian reasons, an empirical claim could be made in support of wealth tax.

It is to assert that individuals and collective entities benefit from public goods and services in proportion to their wealth. For instance, large fortunes benefit materially much more from the stability offered by a functioning state, rule of law, police, and judicial system, than poor citizens. Furthermore, it could be argued that large accumulations of wealth remain difficult (except for few individuals) in societies without a functioning state because of the difficulty to protect large properties against envious behaviors. Therefore, rich individuals should contribute more in absolute terms (and also perhaps relatively to their wealth through a progressive tax) than poorer ones.

However, there is an issue of efficiency. Public institutions may experience difficulties to adequately evaluate taxpayers' wealth due to the various forms taken by wealth (money, financial assets, real estate properties, company stocks, and so forth), but also due to the extended possibilities for fiscal evasion (e.g., by locating bank accounts in tax havens, by using dummy persons or shell corporations).

This explains the popularity of taxing wealth when wealth is passed on from one legal proprietor to another. Since for enjoying wealth, individuals and entities need, at some point, to declare it for guaranteeing their rights, one technique consists in taxing wealth when property is transferred. An example is inheritance tax, which is to tax individuals who receive wealth from someone else (usually deceased). However, the problem of misdeclaration and concealment of assets exists for wealth too.

Another argument supports taxing inherited wealth: the fact that the receiver from wealth has a less strong claim to the enjoyment of such resources. If it is reasonable to assume that in many cases the original owner owed its material affluence to her or his work, such a justification is lessened in the case of the receiver. It is more difficult (although not impossible) to argue that the heirs have *deserved* or *merited* their wealth.

As for the previous bases, wealth taxation needs to answer some objections, which for most of them mirror the objections addressed to income tax. On the one hand, individuals should be entitled to the accumulated fruits of their labor. On the

other hand, taxing (too heavily) wealth could have a disincentive effect on work, lead individuals to underreport their wealth, or leave the country for a more fiscally lenient destination. This last point opens the question of fiscal competition between states.

The Tax Structure

Most of the debates surrounding fiscal ethics have actually more to do with how to tax rather the tax bases in themselves. The issue raised by *how to tax* relates to the tax structure, i.e., the different tax brackets. This is a technical issue. However, the key idea underlying the choice of a tax structure is how to distribute the tax burden across a population? More precisely, it is about fair calculations of one's tax duties.

Taxes can be levied in three main forms: lump sum, flat, and progressive. A lump-sum tax is fixed amount imposed to all taxpayers. Examples include poll taxes, public toll roads, tourist taxes (fixed amount paid per night and collected by hotels), etc. Lump-sum taxes have the virtue of simplicity. They are easy to calculate (a single amount) and implement. However, such simplicity has shortcomings. It lacks flexibility, especially when public institutions are searching to design a structure that is responsive to taxpayers' situations (e.g., ability to pay) and behaviors (e.g., excessive consumption, increased wealth or income). It is also highly regressive, i.e., the rate of taxation decreases in relation of taxpayers' resources. Toll roads are less burdensome for wealthy drivers than modest ones.

A flat tax applies a fixed rate to all taxpayers on their income, wealth, inheritance, benefits, expenses, consumption, or something else and independently of their situation (e.g., affluence). Examples of flat taxes are VAT (although in some countries VAT has several brackets, e.g., on luxury products) and income tax (e.g., in many post-communist countries). The main advantage of a flat tax is the simplicity of calculation and implementation. Its main drawback is its regressivity. It is more burdensome for materially vulnerable people. Although the proportionality guarantees that taxpayers' contributions are sensitive to their material situation, it is insensitive to inequalities.

A progressive tax is structured around several rates (or brackets) depending on taxpayers' material situation. Examples of progressive taxes include income tax in many industrialized countries. The idea is to increase the fiscal burden in relation to one's resources based on the ability to pay. Depending on the design of brackets, progressive taxes can have strong redistributive effects. If this aspect is valuable from an egalitarian perspective, it also implies that (steeply) progressive taxes are less likely to be accepted by the most affluent taxpayers.

Summary

Fiscal ethics encompasses analyses of the design of a tax system. The objective is tax fairness, i.e., a tax architecture that can be judged as just by the taxpayers. In detail, fiscal ethics cover three main issues: *why taxing*, i.e., why public institutions are legitimate to capture part of individuals and organizations' material resources; *what to tax*, i.e., on which base (mostly income, consumption, or wealth) to levy taxes or, more accurately, how to spread the fiscal burden across bases; and *how to tax*, i.e., concretely how to implement taxes, especially how to calculate different taxes (lump-sum or fixed amount, a flat rate or different rates included in a progressive architecture). When considering these issues, fiscal ethics can mobilize political principles such as equality or efficiency that needs to be precisely defined.

Definition

Defining fisheries is not a straightforward task. It involves several components that make its definition context-dependent. They are usually determined based on the manner of production, type of aquatic habitat, the section of the marine habitat targeted, type of gear used, method of fishing, class of boats, fish species (or assemblages) targeted, and scale of production. In fisheries science, a fish is not restricted to the biological definition of an organism with a backbone, gills, and fins. Fish instead refers to all the natural aquatic resources that can be subtracted. Finfishes, however, tend to be the most abundant and vital. Therefore, a fishery (plural; fisheries) refers to any activity or entity involved in fish rearing or harvesting. Simply put, it is an arrangement that consists of the raising of fish, also called culture fisheries, or the harvesting of fish from the wild also referred to as capture fisheries. It is also considered an entity engaged in raising or harvesting fish, which is determined by an authority.

Introduction

Fisheries are a critical part of social existence because they contribute to the economics and livelihood of people in the World (Canty and Deichmann 2022; Whitfield et al. 2022). This activity involves capturing, rearing, and processing fish products with ubiquitous uses and benefits such as subsistent and small scale, recreational and touristic, and commercial and industrial. There are about 60 million people involved in fisheries, including capturing fish from the wild and restricted rearing of the fish (FAO 2018). Globally, Asia has the highest participation in fisheries, and Latin America and the Caribbean are the least regarding their involvement in fisheries (FAO 2018). The main aim of fisheries is to achieve maximum and continuous production, referred to in fisheries science as the Maximum Sustainable Yield (MSY), which the World nations have committed to pursue in fisheries through the *Law of the Sea* (Martell and Froese 2013).

Fisheries may be commercial or industrialized, mostly large-scale artisanal, primarily small-scale, subsistent, recreational, and ornamental. Commercial fishing involves the exploitation of wild fish resources, usually from the deep sea or broad pelagic areas (e.g., Tuna fishery), contributing to the supply of fish demand (Canty and Deichmann 2022; Griffiths et al. 2019). Artisanal fisheries use low-technology gears to catch inland and coastal fisheries resources; it also implies traditional fishing practices and is usually practiced by individual fishing households. Recreational fisheries, also called sport fishing or angling, are defined as the art of fishing for pleasure (Hughes 2015). Ornamental fisheries refer to unique fishes admired for their color and beauty.

Fisheries can be classified based on habitat and salinity as marine, brackish, and freshwater engaged in habitats such as sea, ocean, river, lakes, wells, and ponds, all affecting the chemical and biological nature of the seafood caught from the exercise (Wijayanto et al. 2021). Marine fisheries are conducted in habitats of salinity of around 35ppt (parts per thousand in all oceans and seas across the globe), without neglecting estuarine regions where salty oceans and rivers meet, mangroves, and reefs (Wijayanto et al. 2021). In comparison, marine fisheries occupy the largest share of seafood produced globally. Brackish fisheries are conducted between 0.5 and 30 ppt in water bodies with high salinity but lower freshwater values (Wijayanto et al. 2021). In contrast, freshwater fisheries are done in salinity habitats of 0.5ppt or less (Dyldin et al. 2020; Morita 2021).

Types of Fisheries

The fundamental definition of fisheries comes from the interaction between fishes and other invertebrates (fish, hereafter) in the marine environment (Cashion et al. 2018). Fisheries provide 17% of the total animal protein consumption across the World, and its importance has been increasing during the last years. However, global capture fisheries have remained relatively static (surrounding 90 million tonnes) for the previous

40 years (FAO 2018). The latter might be explained by the limited production rate of exploited populations, which is conditioned to population size and the ecosystem's carrying capacity (Schaefer 1991). The carrying capacity is related to the extension of ecosystems, and it increases with distance from shore, from inland to the open ocean. So the distance from shore modifies the level of technology (cost, effort) involved in the fishing process (Islam et al. 2022; Whitfield et al. 2022).

On the other hand, technology implied for fishing varies with the degree of economic development of the ventures to pursue highly valued fishery resources. Thus, relevant differences in fish production exist between developed and developing economies, inland and marine ecosystems, demersal and pelagic fisheries, and the ecosystem impacts related to each fishery. Fishing gears, defined as *"the equipment used for fishing,"* can be classified by several factors, however, considering that technology implied in the fishing process is related to the effort needed and the scale of the catch. Then, we use technology as the main classifying factor, from artisanal to highly industrialized fisheries (FAO 2009).

Artisanal fisheries could be defined as low-technology fisheries (Rousseau et al. 2019a). This sector is often referred to as small-scale fisheries. It comprises a wide variety of fishing-gear categories: bag nets, cast nets, hand/tools, encircling nets, gillnets, lines, pots or traps, seines, and many other kinds of nets or tools that vary regionally (Cashion et al. 2018). This sector contributes to ~25% of the catch in volume but 90% of employment in capture fisheries (FAO 2018) and the global number of vessels (Rousseau et al. 2019b).

Industrial fisheries (large-scale) imply much more technology in the fishing process, higher catches, and more sophisticated preservation methods. The fishing gears used in large-scale fisheries refer to bottom and pelagic trawls, long-lines, purse seines gillnets, and many others, including dredge, pots or traps, and a mixture of fishing gears (Cashion et al. 2018).

While artisanal fisheries provide more than 50% of animal protein consumed in developing

countries at affordable prices, industrial fisheries look for higher-valued species. For example, the bluefin tuna (*Thunnus thynnus*) can reach prices of 547 €/kg in Japanese markets (Mylonas et al. 2010). Also, fisheries employ 40.4 million people (FAO 2018). However, despite their social and economic benefits, global fishing still faces several management issues such as illegal and unreported fishing (IUF), bycatch, discards, habitat alteration, and air and ocean pollution.

Key Issues

There is a strong correlation between governance and IUF, and unfortunately, there is not a comprehensive policy to govern the high seas, which comprises 60% of the marine environment (IUCN 2020). Also, IUF can represent 40-60% of reported catches in developing countries (Agnew et al. 2009; Cisneros-Montemayor et al. 2013). Additionally, IUF is closely related to the catch of protected species (e.g., *Totoaba macdonaldi*) that compromises survivorship of species in danger of extinction as the Mexican porpoise. However, bycatch of nontargeted marine species occurs in legal fisheries too. It threatens charismatic species such as sea turtles, seabirds, marine mammals, and sharks, along with species of ecological importance but without market value (Cambiè et al. 2020; Glemarec et al. 2020; Peltier et al. 2016).

Another critical issue is the discards, defined as marine species that are thrown overboard because they have no market value, are too small, damaged, or inedible, discards surround 10 million t per year (Zeller et al. 2018). It just does not represent a waste of potential source protein (for direct or indirect consumption). It contributes to altering ecosystem structure while adding food for small predators and scavengers and reducing oxygen availability due to its decomposition.

Any fishing gear inherently interacts with the physical environment. However, the impact of that interaction depends on many factors, such as the gear configuration, towing speed, depth, and type of substrate. The effects of fishing in marine habitats include unintentional mortality of marine

species, loss of physical structures used for shelter, feeding, or mating, the resuspension and burying of organic ions and organic material, and the reduction of resilience and biological productivity (NRC 2002, Kraus and Diekmann 2018).

Also, the high use of fossil combustibles (706 L of fuel per one tonne of fish caught, on average) contributes to air pollution (Parker and Tyedmers 2015). Also, fishing vessels contribute to marine pollution through plastic garbage thrown into the ocean or ship casualties, although its contribution remains unclear (Jambeck et al. 2015).

Fisheries Management and Policy

Fisheries management is a complex process of gathering, analyzing, planning, deciding, allocating resources, formulating, and enforcing fisheries regulations. It is usually controlled by the designated fisheries management authority in control of the immediate and future activities of interested parties to ensure sustainable productivity of the natural resources. Recent developments have motivated the improvement upon the previous concept of management, which focuses on single fisheries or single fisheries necessitating an ecosystem undertone. A broader approach referred to as ecosystem-based fisheries management (EBFM). As its name implies, it involves the integration of ecosystem consideration in management, leading to more effective ecosystem conservation and sustainability.

Fisheries and Sustainable Development Goals (SDGs)

The SDGs goals and structures are necessary to fisheries, particularly the 14th SDG (life below water), i.e., conserve and sustainably use the oceans, seas, and marine resources for sustainable development. The goal is linked with all the other purposes because fisheries are considered an interdisciplinary area of food security. The goal ensures that fish harvesting should be regulated and overfishing IUU (illegal, unreported, and

unregulated) fishing, including destructive fishing, should be stopped. The ultimate goal is to restore fish stocks to produce the best maximum economic yield and maximum sustainable yield, which can be achieved with science and policy-based management plans. Furthermore, the goal considers avoiding subsidies on fisheries that lead to excess exploitation, increasing the economic benefits of emerging and least developing countries from the sustainable use of fisheries resources, and therefore, not limiting the empowerment of the access right of small-scale fisheries, adhering to all local, regional, and international laws and provisions (FAO 2018).

Summary

No doubt, the world depends so much on fish which is among the essential living resources. Total 15% of protein needs is supplied by finfishes globally, and over 90 million tons of finfish is exploited from the wild (Ormerod 2003). Fishes are incredibly diverse, making them highly relevant and ecologically essential in conserving aquatic resources, managing the marine ecosystem, and regulating its environment. Paradoxically, there is an increasing development of management challenges that negatively impact production, available stocks, quality of habitat, global diversity, trophic structure, and composition of fish communities. Although these challenges are natural or anthropogenic, anthropogenic influences are usually more impactful and even pave the way for biological impacts. The main problems of freshwater bodies include pollution, alien fish introduction, habitat modification, water flow obstruction, and dam regulation, among others. For marine systems, direct and overexploitation affects the habitat and the fish and other aquatic life. The environment is linked to the marine habitat, such as the atmospheric, terrestrial, and coastal impact on the water or habitat quality. Climate change is currently influencing and is predicted to impact more seriously on fisheries and aquaculture in the future, especially in vulnerable areas. Lastly, for fisheries to be sustainable, there is a need

to not only improve data quality to reinforce governance and social inclusiveness in fisheries but strengthen international regulations for trawling and other fishing exploitation activities and promote blue growth at the local, national, regional, and international levels under the context of the ocean decade of action.

Introduction

In addition to other marine resources, the West and Central African façade of the Atlantic Ocean is abundantly rich in fish biomass (UNEP 2016; Okafor-Yarwood 2019; Okafor-yarwood et al. 2020), with countries having several shared fish stocks. However, myriad challenges confront the sustainability of these resources including over-fishing by foreign vessels; poor management of fisheries stocks; low participation of stakeholders in fisheries management; and illegal, unregulated, and unreported fishing (IUU fishing) activities. Overcoming these challenges in a sustainable manner, therefore, calls for regional as well as international cooperation. In line with this need, the Fisheries Committee for the West Central Gulf of Guinea (FCWC) (*Comité des Pêches pour le Centre-Ouest du Golfe de Guinée*) was established in November 2007 by

the Cotonou Convention as an intergovernmental organization to promote regional cooperation among its member and ensure sustainable management and conservation of marine resources under the national jurisdiction of its Contracting Parties. The six countries that make up the FCWC’s membership include Benin, Cote d’Ivoire, Ghana, Liberia, Nigeria, and Togo. Equipped with the capacity to enhance policy and institutional reforms, and the commitment to garner support for regulations and improved governance, the FCWC has since inception remained on the frontline of rebuilding and maintaining robust fisheries resources, creating sustainable livelihoods for small-scale fishers and improve intra-regional and international trade of fish and fishery products within its jurisdiction. The FCWC’s area of competence covers the Territorial Seas and the Exclusive Economic Zones (EEZ) of its member states (Fig. 1). Its

F

Fisheries Committee for the West Central Gulf of Guinea (FCWC), Fig. 1 Competence area of the Fisheries Committee of the West Central Gulf of Guinea (FCWC). (Source: FAO 2020)

activities are conducted in English and French language, and its Secretariat based in Tema, Ghana.

The History

The journey to establish the FCWC started in July 2005 during the sixth meeting of the Ministerial Conference on Fisheries Cooperation among the African States bordering the Atlantic Ocean (COMHAFAT) in Rabat, Morocco, when the United Nations Food and Agricultural Organization (FAO) was asked to evaluate the possibility of establishing a subregional committee of fisheries in the west-central part of the Gulf of Guinea. FAO acceded to this request and seven months after (March 2006) the organization had produced the feasibility study which was later reviewed at a meeting held in Cotonou, Benin Republic on the 12th–13th of April 2006 by the fisheries directors of Benin Republic, Cote d'Ivoire, Ghana, Liberia, Nigeria, and Togo. Following the review, the six directors approved the project to establish a subregional committee of fisheries, called the Committee of Fisheries for the West Central of the Gulf of Guinea (FCWC).

To solidify the fisheries directors' approval, a ministerial meeting was held in Abidjan, Côte d'Ivoire, in July 2006, to accept the proposals. It was eureka, as the Ministers unanimously signed what is now known as the "*Declaration of July 2006, establishing the Committee of Fisheries for the West Central of the Gulf of Guinea (FCWC)*", and also approved the hosting of its Secretariat in Tema, Ghana. Following these events, the first Ministerial Conference of November 2007 in Cotonou, Benin Republic, approved the "*Convention for the Establishment of the Fishery Committee for the West Central Gulf of Guinea*" as well as the "Rules of Procedure of The Fisheries Committee for West Central of Gulf Guinea."

Mission, Objectives, and Focus Areas

The FCWC is poised to promote authentic transnational cooperation between countries within

its jurisdiction, to foster effective management, appropriate conservation, and development measures capable of ensuring sustainable development of fisheries resources. The FCWC activities are predicated on an overarching goal "to ensure the sustainable development of the fisheries resources in the FWC Convention Area"; driven by five "strategic technical" goals/objectives, and one "strategic functional objective which guides the specific intervention areas under its 2011–2020 Strategic Plan (FCWC 2020).

The objectives put together include:

1. Rebuild and maintain robust fisheries resources through policy reforms, cooperative regulatory planning, good governance, and improvements in institutions.
2. Develop and implement appropriate management frameworks that ensure fisheries resources are harvested sustainably, improved intra-regional and international trade of fish and fishery products, and maximum economic and social benefits are obtained from the fisheries.
3. Develop the capacity of Members' small-scale fishers and other operators to create sustainable livelihoods for their people from the sustainable harvest, processing, and marketing of their fisheries resources.
4. Enhance national capabilities for efficient, cost-effective, and sustainable fisheries monitoring, control, and surveillance, and establishing mechanisms for effective regional cooperation in Monitoring, Control and Surveillance (MCS) and enforcement to stop illegal, unreported, and unregulated (IUU) fishing in the West Central Gulf of Guinea.
5. Strengthen cooperative research and ensure that resource-related decisions are based on sound knowledge, scientific methodology, and best information available.
6. Our Strategic organizational/functional goal is "To ensure the effective implementation of the Committee's work through results-based management, improved communication, and better financial, human and knowledge management systems and tools."

Structure of Governance

The 2007 Convention that established the FCWC and its Rules of Procedure has explicitly laid down organizational competences of different governance structures of the FCWC. The Conference of Minister or Ministerial Council stands as the apex decision-making component of the FCWC's governance structures; followed by the Advisory Coordinating Committee (ACC) made up of one Directors of Fisheries nominated from each Contracting Party; and a Secretariat that is composed of Staffs who coordinates and run the everyday affairs of the FCWC (Fig. 2).

Rule 15 of the FCWC's Rules of Procedure leaves the final decision-making power in the hands of the Conference of Ministers by consensus. However, rule 16 of the same Rules of Procedure specified otherwise in the occasion that all efforts to decide by consensus have been exhausted, and as a last resort, a decision can be taken via the majority of votes by Contracting Parties present. The ACC is duty-bound (under article 9.5 and 10 of the Convention) to hold regular meetings at least twice a year, preferably at its headquarters in Tema, Ghana, and the second meeting in the country hosting the Conference of Ministers. Pursuant to article 9.4 of the Convention, the position of Chairperson of the ACC shall be held by the representative of the Contracting Party holding the chairmanship of the Conference of Ministers at the time of the meeting.

The Secretariat serves as the executive arm of the FCWC and performs its functions according to functions stipulated in article 12 of the Convention. The Secretary-General is appointed by the Conference of Ministers for a period of 5-years renewable and must be a national from one of the Member States. S(He) runs the everyday affairs of the FCWC secretariat including staffing and ensures that Contracting Parties are informed of any issues or matters which may be of interest to the FCWC including the communication of the annual report to the Contracting Parties and to observers at least 30 days before the opening of the regular meeting.

Activities and Major Accomplishments

As the need for a continuous mechanism of funding is necessary to sustain the activities of the FCWC's Secretariat, the structure of the Secretariat and a permanent funding mechanism to support the FCWC's activities was adopted in 2008. Acknowledging the menace posed by IUU Fishing within its jurisdiction, Fisheries Ministers in the six countries converged in Accra in 2009 to proclaim the "*Ministerial Declaration of Accra, combating illegal fishing and adoption of the regional action plan against illegal fishing.*"

On 13 December 2013 marked another milestone in the unwavering commitments of the FCWC towards sustainable management of

Fisheries Committee for the West Central Gulf of Guinea (FCWC), Fig. 2 Organizational structure and decision-making loops of the FCWC

fisheries resources under its competence, as the “Convention on minimum requirements for access to the fishery resources of the area of the fisheries committee for the West Central Gulf of Guinea” was adopted by Ministers of Fisheries from the six member states. Acknowledging the importance of transnational data and information sharing in enhancing sustainable fisheries management, another landmark “*Convention on the pooling and sharing of information and data of the area of the FCWC*” was adopted in Abidjan on 12 December 2014.

Acknowledging the FCWC as a thorough intergovernmental organization, the Parliament of the Republic of Ghana on 7 December 2015 ratified the headquarters agreement of the FCWC, listing the immunities, privileges, exemptions, and facilities granted to the organization – giving the organization a legal status similar to that of a diplomatic corps, empowering it to be functional and achieve its objectives as an intergovernmental institution.

The development of a strategic plan from 2011 through 2020 to guide the FCWC’s activities marks a great milestone and a clear indication of the Committee’s giant strides in ensuring fisheries and marine sustainability within its area of jurisdiction. The thoughtfulness and quality within the process, tactical and operational aspects of the strategic plan, unequivocally affirmed that the FCWC is truly on the path of driving the region towards sustainable fisheries and blue economy development in the region. Apart from working on the 10 projects that have been identified for the implementation of its strategic plan, the FCWC has also continued engagement with regional and international partners on several other related projects including: Building Transparency in West Africa; Fisheries Intelligence and Monitoring Control and Surveillance Support in West Africa; Improved Regional Fisheries Governance in West Africa; etc.

and changed the context of fisheries sustainability, and how achieving it must be addressed in West and Central Africa. The FCWC is achieving this by promoting a sustainable development path as an overall strategy and adopting an ecosystem approach to fisheries management that put sustainability as the primary agenda item. Overall, the FCWC has fostered a process where strategic regional choices are made by relevant national fisheries authorities, based on common challenges, and has been able to adapt these interpretations to fit the political and economic context in which they work. In doing so, the FCWC is reconstructing national and regional policy agendas to take account of human capital needs, information technologies, and environmental issues.

[Framework for sustainability](#)

Definition/Description

The Five Capitals model developed by the Forum for the Future assists companies in devising sustainable strategy and assimilation of sustainable initiatives in their management practices (Forum for the Future, [n.d.-b](#); Sitnikov, [2013](#)). The model “provides a basis for understanding sustainability in terms of the economic concept of wealth creation or ‘capital’” and links company to the external environment in the long run (Forum for the Future [b](#)). Through the model, a company can develop a vision of sustainable operations, products, and services, all with the goal of value maximization. The interdependence of the five capitals is well established, so any modification of one can have a profound impact on other capitals. Many organizations utilize the model to develop the strategy, while stating their goals and operationalizing them through Sustainable Development Goals (SDG) goals or Environmental, Social, and (Corporate) Governance (ESG) ratings. The model stood the test of time and remains prevalent concept for understanding countless seeming unrelated subjects and overall sustainable activity.

Forum for the Future

The Forum for the Future is one of the leading global sustainability initiatives (Forum for the Future, [n.d.-a](#)). This English nonprofit organization has been working with businesses, governments, and societies on numerous sustainability issues for over 25 years. Most recently, their focus was shifted by five key dynamics: biosphere breakdown, economics crisis and reform, tech and governance nexus, equitable transitions, and regenerative openings (Forum for the Future, [2020](#)). The mentioned dynamics are destabilizing the sustainability systems, and seriously altering years of hard work. Most notably the Forum for the Future developed the framework for sustainability called The Five Capitals Model (Forum for the Future [b](#)).

The Five Capitals Framework

Many organizations utilize the five capitals framework to develop or shape their sustainability strategy. The five capitals model calls for sustainable wealth creation or “capital” (Ivory & Ascui, [2019](#)) in contrast to the Friedman doctrine (CFI, [2022b](#)). Organizations use five types of capital: natural, social, human, manufactured, and financial for the creation of products or services (Forum for the Future, [n.d.-b](#); Owen & Kemp, [2012](#); Porritt, [2012](#)).

The Five Capitals Model

Organizations use five types of capital to create products or services and attempt to maintain or even enhance the capitals. The model entices organizations to consider how different capitals influence each other and how they impact long-term profitability.

Natural capital, also known as environmental, is the natural resources. All organizations rely on natural capital as they need energy and have an environmental impact as they create waste. Organizations should consider that some resources are not renewable (i.e., oil, gas), while others are

(i.e., timber, water, and grain), and with that in mind, try to organize more balanced operations. Further, organizations can enhance natural capital by recycling, reusing, substituting scarce materials with more abundant ones, using renewable energy sources, etc. The importance of such goals is emphasized in the 2030 Agenda for Sustainable Development which was adopted unanimously by the 193 members of the United Nations (UN) in September 2015 (The Grantham Research Institute on Climate Change and the Environment, 2018). The agenda was operationalized through the 17 Sustainable Development Goals (SDG) and 169 targets (United Nations, [n.d.-c](#); United Nations, [n.d.-d](#)) widely used by both private and public sectors across the world. The following SDGs are focused on environment and natural resources:

- Goal 12: Responsible Consumption and Production
- Goal 13: Climate Action call for action to combat climate change and its impacts
- Goal 14: Life Below Water
- Goal 15: Life on Land

Human capital includes health, skills, knowledge, intellectual contributions, motivation, etc. Organizations depend on a workforce to function, so they want to ensure individuals are healthy, motivated, skilled, and ready to work. To maintain and enhance human capital, organizations should invest in their workforce, provide training and education, provide fair compensation, create opportunities for advancement, support a high standard of health, and so forth. Several SDGs (United Nations, [n.d.-a](#); [n.d.-d](#)) address these issues, including:

- Goal 3: Good Health and Well-being. The goal is tightly connected to goal 1: No Poverty, goal 2: No Hunger, and goal 6: Clean Water and Sanitation.
- Goal 4: Quality Education.

Social capital is a value added to economic output through human relationships, such as networks, communication channels, communities, schools, and similar. These social relationships are necessary for organizational effectiveness.

Inside the company, individuals build trust through interactions and share cultural values, and ultimately organizations operate effectively. Social interaction is equally important in the external environment, as companies operate in the wider society. Organizations can enhance their social capital by being responsible, paying taxes, obeying laws, minimizing negative social impact, providing safe working conditions through ethical sourcing, and so on. Goals (United Nations, [n.d.-b](#); [n.d.-d](#)) corresponding to this type of capital are:

- Goal 5: Gender equality
- Goal 8: Decent Work and Economics Growth

Manufactured capital includes real estate, infrastructure, and technologies owned, leased, or controlled by the organization. Organizations can sustain competitive advantage through manufactured capital while improving efficiency and sustainability. Some of the measures organizations can use to grow their manufactured capital include modular manufacturing systems, zero-waste and zero-emission production systems, reverse logistics with the remanufacturing system, industrial ecology, etc., many of which are represented in the following SDGs (United Nations, [n.d.-d](#)):

- Goal 7: Affordable and Clean Energy
- Goal 9: Industry, Innovation and Infrastructure
- Goal 11: Sustainable Cities and Communities

Organizational assets in the form of currency that can be owned and traded compose financial capital. They typically include notes, shares, and bonds and reflect the power of other types of capital. Financial capital is the traditional measure of business performance. Sustainable organizations have to understand how economic value is generated. Organizations can enhance financial capital by distributing created wealth, building strong supplier and customer relationships, effectively managing risk, building brand and reputation, and so forth. One of the SDGs (United Nations [d](#)) related to the financial capital is:

- Goal 10: Reduced Inequality

The final goal, goal 17: Partnerships for the Goals (United Nations, n.d.-e, para. 2), is focused on facilitation of the sustainable development goals, through global partnerships and joint responsibility of all stakeholders. As mentioned at the beginning, the mentioned 17 goals have 169 interrelated and often interdependent targets, so clearly many goals could be related to the several capitals.

The five capitals model remains at the core of conceptual framework, yet the SDGs are more apparent in many organizations. The most common is Environmental, Social, and (Corporate) Governance (ESG) rating, adopted by numerous agencies. Many millennials are investing in companies that are more closely aligned with their values, and often pursuing socially responsible investing strategy (Corporate Finance Institute, 2022a). As the proportion of millennials is growing in total number of investors, so is the importance of ESG ratings. Even though ESG ratings are quite popular, they are quiet immature, relative, and not standardized. Companies are using different approaches for forming their ESG score: Some are more data-driven, while others are based on analyst's judgment (Bloomberg, n.d.; Hale, 2021).

Summary

In this entry, the Five Capitals Framework originally developed by the Forum for the Future is presented. The importance of the framework is emphasized given its principal conceptual clarity. The framework remains a predominant tool for developing sustainable strategy within organizations. Often it is operationalized though different approaches like SDG goals or ESG ratings. Standardization of ratings remains the biggest challenge in the future.

Definition

Food security is a situation that exists when all people have physical, social, and economic access to sufficient, safe, and nutritious food at all times that meets their nutritional needs and nutritional preferences for an active and healthy life (Berry et al. 2015). At the household level, food security means access to enough food for an active and healthy life by all members of a household (FAO 2019). Overall, food security requires at a minimum: availability of foods that are adequately nutritional and safe for consumption; assured ability to possess such foods in a socially acceptable manner (i.e., without acquiring the foods through coping strategies as emergency supplies, aid, scavenging, stealing, etc.) (Coleman-Jensen et al. 2019). This definition includes four main dimensions of food security, namely availability, access, use, and stability (Fig. 1). Food availability refers to the extent to which food is physically or potentially present, including aspects of production, reserves, markets and transport, and wild food. It refers to sufficient quantities of food of appropriate quality, supplied through domestic production or imports, including food aid. The second dimension is access to food. If food is present or is potentially present, another key question is whether households and people have sufficient access or not, or whether they have adequate resources or rights to obtain adequate food for

Food Security, Fig. 1 The pathway of the dimension of food security. (Source: Adapted from Matemilola and Elegbede 2017)

nutrition. A third dimension is the use of food, which refers to the question of whether households maximize the consumption of adequate nutrition and energy. The last dimension is food stability, which refers to the condition in which a population, a household, or an individual has food security (i.e., all other three dimensions are present) at all times (Behnassi and Yaya 2011; Matemilola and Elegbede 2017).

Background to the Concept of Food Security

In 1991–1992, 1.2 billion people were malnourished worldwide, dropping to 991 million in the 2000s and 821 million in 2018 (FAO 2019). However, the number of malnourished people (i.e., those facing chronic food shortages) has increased in the past 3 years. The UN FAO has blamed the growing number of undernourished population on the rising rate of conflicts especially in the developing parts of the world and climate-related factors such as the El Niño phenomenon (Roser and Ritchie 2020). Food insecurity is one of the most significant problems in the world today. In fact, for many countries, food security remains a major challenge. Despite positive economic progress, widespread hunger problems are often overlooked. As can be inferred from the State of the World’s Food and Nutrition Report (SOFI), treating sufficient, safe, and nutritious

food to maintain an active and healthy life is a major challenge for society today. As of early 2019, FAO report reveals that global prevalence of undernourishment stands at 10.8% which implies that 821.6 million people are undernourished. The report further reveals that Africa is the worst hit part of the world with starvation at prevalence level of 19.9% while Northern America and Europe have a combined prevalence of less than 2.5% (FAO 2019). Conflicts in Yemen, Nigeria, and South Sudan have devastated homes and increased food prices, while a drought in Somalia has destroyed the agricultural economy. In an extreme case, those facing severe starvation can lose their lives. Dominic Macrorley, CEO of Concern Worldwide, said that “as the world progresses in the fight against hunger, around 800 million people are still condemned to hunger every day” (Roser and Ritchie 2020).

The pioneer work in the study of linkage between food security and population dates to 1798 when Reverend Thomas Robert Malthus published his writing “An Essay on the Principle of Population” which promoted the concept of Malthusianism. Malthusianism is built on the theory (Malthusian theory) that population growth is potentially exponential while food supply growth is linear. Malthusian theory establishes that there is a food shortage due to the presence of too many people in relation to the amount of food supply and, therefore, exacerbated long-term food insecurity (Smith 2015). It has been shown overtime

that a growing population accompanied by a growing demand for more food contributes to the undernutrition of the whole population. For example, it has been found that significant increases in several populations lead to increased use of water and land, which in turn affects agricultural productivity. Likewise, a recent survey points out that population growth will have a major impact on food availability and will contribute to food conflicts, especially in the north and center of South America, in sub-Saharan Africa, and in Southeast Asia (Etana and Tolossa 2017; Campbell et al. 2016).

The term “food security” first emerged at the World Food Conference in 1974. At the conference, food security was defined in terms of food supply as “assuring the availability and price stability of basic foodstuffs at the international and national levels” (Matemilola and Elegbede 2017; Brown 1981). The concept of food security has however evolved since the 1974 World Food Conference with the most recent definition emerging at the World Food Conference of 2009 in what is now generally considered the standard definition of food security. Food security is now considered to exist when “all people, at all times, have physical and economic access to sufficient, safe and nutritious food that meets their dietary needs and food preferences for an active and healthy life.” This definition introduces the four dimensions that illustrate the pathway of food security from the food production stage (availability) to household (accessibility) to individual (utilization) and the consistency thereof (stability) (Fig. 1) (Berry et al. 2015; Tian et al. 2016; FAO 2011).

Challenges to Food Security

Food security has become an issue of serious concern for governments and policy makers as it affects the lives of millions of people across the world. The following are some important factors that constitute barriers to food security:

I. Population Growth

Population has perennially been a key driving force for many environmental and resource challenges (BCFN 2010). While

history has established that the global arable land size is fixed, the world population has continued to grow at an alarming rate especially in countries of the global south. However, population growth means increased pressure on food supplies and the fixed cultivable land. Thus, despite the growth in the total global grain production, there has been downturn in the amount of grain per person and total grain reserves (Behnassi and Yaya 2011).

II. Politics and Corruption

Politicians often recognize the importance of food security and how much a prevalent hunger among their subjects can subvert their public acceptance. However, they are often caught in the middle of addressing the public needs and the demands of the powerful corporate firms and vested interest of other nations since public food sufficiency may not imply corporate profit sufficiency and may reduce dependence on other big nations. Thus, international and corporate lobbying especially in the developing countries greatly influence agricultural policies in a way that favors the interests of industrialized powerful countries and corporate organizations (BCFN 2010).

III. Inadequate National and International Policies

Many countries are being ravaged by poverty and hunger not because of lack of resources but due to inefficient policies relating to agriculture, local and international trade, and other support sectors. Such poor policies that have affiliation with agriculture can have devastating effect on food security as hunger and malnutrition may persist or even worsen (Behnassi and Yaya 2011). Therefore, the development drive of many countries has failed on the back of poor policies and initiatives in sectors that have interdependence with agriculture causing food prices to rise, production to dwindle, or inaccessibility (Matemilola and Elegbede 2017).

IV. Climate Change

The phenomenon of climate change has become an important driver in the global food equation playing a significant role in the food security of many countries especially in the less developed nations. Climate change

is affecting the global temperature and biophysical feature of many regions making it difficult for farmers to predict seasonal patterns. This situation is affecting crop yield and stability of food supplies (Behnassi and Yaya 2011). Though, the developed economies are guilty of contributing the major share of global emission, and with the emerging economies such as China, India, and Brazil towing similar path, the implication of the less developed countries is expected to be more devastating than ever (Campbell et al. 2016).

V. Conflicts and Insecurity

Postindependence wars, civil conflicts, and insurgency create a sense of insecurity. In many parts of the world especially in the less developed regions, armed conflicts have been on the rise interrupting food production and causing displacement of agrarian communities. In many of the conflict-affected countries, a significant proportion of the households and farms are small-scale or subsistence farmers, who are usually confronted with high degree of income uncertainty while some households are engaged in agricultural commodity supplies. In this case, any form of armed violent conflict will create shock that will interrupt the socio-economic fabric of this region. Such conflicts depending on the magnitude can lead to destruction of farmlands or cause farmers to vacate their farmland for safety. Also, where economic activity of the region is affected, people have less disposable income making food items less affordable and increasing prevalence of food insecurity (Martin-Shields and Stojetz 2019).

Summary

Food security as a concept originated in 1974 at the World Food Conference, where the global leaders had gathered at a time of food crisis to discuss international food problems. At this time, food security was primarily considered in terms of food supply problems – of assuring the availability and to some degree the price stability of basic foodstuffs at the international and national level. However, the concept of food security has

evolved and expanded since then to incorporate at a minimum the availability of foods that are adequately nutritional and safe for consumption as well as the assured ability to acquire such foods in a socially acceptable manner. However, food security faces a number of challenges including inadequacy of agricultural and food practices and policies, climate change and global warming, international and local politics and corruption, and civil conflict and insecurity.

Description

Some timber traders as well as social and environmental non-governmental organizations (NGOs) negotiated the establishment of the Forest Stewardship Council (FSC) in San Francisco in 1991 (Cadman, 2011). Two years later, representatives from ten countries met in Toronto, Canada, for the founding meeting of the FSC. Finally, as a result of the intensive negotiations, the FSC was registered in 1994. It created a new model of a market-based protection instrument to promote responsible forest management and trade (WWF, 2014/2020). According to Pattberg (2005), the FSC is based on the principles of sustainable development. The standards of responsible forest management defined by the FSC make it possible to promote globally and nationally responsible forest management.

Introduction

Our images of the forest are dominated by a strong aesthetic and ideal if not as romantic charge. For many, the forest is also a soul landscape (Fig. 1). Recreational use of forests is diverse and common. Forests also play an important role in maintaining and sustaining life. Without healthy and well-maintained forests, climate change will intensify, and biodiversity is declining (Fig. 2). The production of bio-based and low-carbon products and services will also be jeopardized.

There is still no globally agreed legally binding agreement to prevent deforestation, although as early as 1992, the United Nations Rio Summit decided to develop a forest management plan to meet the needs of present and future generations. Consultation processes were held in ten countries between 1990 and 1993 to determine the level of support required for the global certification program for natural and plantation forests. The founding meeting in Toronto in September 1993 was attended by 130 participants from 26 countries (Cadman, 2011). The Forest Stewardship Council (FSC) was established the following year. Its first forest certification scheme served as the standard for a new market-based protection

Forest Stewardship Council, Fig. 1 Protected forest. (Photo: Eila Jeronen)

instrument to promote responsible forest management and trade (WWF, 2014/2020). Today, the FSC is supported by several environmental and social non-governmental organizations, and it has served as a model for other certification schemes.

Key Issues

Establishment and Development of the FSC

The FSC is a non-profit, independent membership-based organization that aims to promote responsible forest management around the world through forest management standards, an accreditation or certification system, and trademarks. The FSC was established as a result of strategic discussions with stakeholders in 1993 (Cashore et al., 2007). The chosen strategy satisfied various associations, trade unions, and indigenous interest groups. The founding members included, e.g., the World Wide Fund for Nature (WWF), Greenpeace, and Friends of the Earth. In 2005, the FSC had more than 600 individual and organizational members including large

Forest Stewardship Council, Fig. 2 Management forest. (Photo: Eila Jeronen)

corporations (e.g., IKEA) and well-known environmental organizations (e.g., Natural Resources Defense Council, The Nature Conservancy, Rainforest Action Network, and Rainforest Alliance) (Pattberg, 2005). In 2019, there were a total of 1177 members operating on different continents (FSC, 2019). New individual and organizational members have joined the FSC since then, most recently in early 2021 (FSC, 2021).

Basics of Operation

The FSC enables forest management issues to be discussed and resolved on a country-by-country and global basis. The new global principle sets out three strategies, each with its own goals (FSC, 2021, p. 13) (Table 1).

FSC aims to promote responsible forest management worldwide by encouraging forest owners, foresters, and buyers of wood products to adhere to best social and environmental practices through certification. FSC has succeeded well in its goal, as evidenced by the fact that many boreal, temperate, and tropical forests, which are owned publicly, privately, or by communities, are managed in accordance with FSC standards.

The FSC's work is based on the internationally agreed 10 principles for forest stewardship (FSC, 2004) (Table 1) and 56 criteria that specify the content of the regulations (Cadman, 2011). The principles and criteria define which practices are considered "environmentally appropriate, socially beneficial and economically viable management of the world's forests" (FSC, 2006, p. 1; FSC,

Forest Stewardship Council, Table 1 The strategies and goals of the FSC Global Strategy 2021–2026 (FSC, 2021, p. 13)

Strategies	Goals
1. Co-create and implement forest solutions	1.1 Engage members and stakeholders to drive change as a community for co-creation of solutions 1.2 Streamline policies and standards toward outcome orientation 1.3 Enhance verification and integrity 1.4 Expand the reach of FSC and its relevance in the fight against climate change and loss of biodiversity
2. Transform markets	2.1 Advance FSC in value chains that have the highest potential for contributing toward our 2050 vision 2.2 Accelerate the market uptake of FSC-certified products and ecosystem services 2.3 Unleash the power of data to demonstrate positive outcomes 2.4 Scale up benefits for indigenous peoples, communities, smallholders, and workers
3. Catalyze change	3.1 Advance the mission through stronger alliances, coalitions, and partnerships 3.2 Increase FSC’s relevance for governments 3.3 Leverage sustainable finance/investment for forest stewardship 3.4 Accelerate awareness of the value of forests

2021, p. 11). Environmental standards apply to, e.g., use of pesticides, harvesting methods, biodiversity conservation zones, and rules on forest conversion (Table 2).

Institutional Organization

The FSC is a membership association operating at national and international levels (Pattberg, 2005) (Fig. 3). The highest organ is General Assembly

(GA) (FSC 2004) which is made up of individual members or delegates of member organizations. GS is held every 3 years, and its task is to discuss and guide the FSC’s activities. The GA is divided into economic, social, and environmental chambers, and each chamber continues to be divided into subchambers (Northern and Southern division) (Cadman, 2011; Pattberg, 2005). The economic chamber consists of either for-profit or non-profit representatives of commercial forestry. The social chamber consists of indigenous peoples’ organizations and social movements. This includes non-profit non-governmental organizations (NGOs) and unions. The environmental chamber is made up of non-profit NGOs whose governing bodies are renewed by regular elections or appointments (Cadman, 2011).

In the FSC, all interests are equally represented, as all chambers and subchambers have the same voting weight (FSC, 2004). The GA elects a director board to which each chamber sends three members for a 3-year term. Representation of northern and southern representatives alternates between four and five, alternating every 3 years. The director board decides on the approval of national representatives, FSC initiatives, and the annual budget and approves new standards. The International Secretariat in Bonn, Germany, is responsible for operational work. Its work is supervised by the executive director (director general), appointed by and responsible to the director board (Cadman, 2011; Pattberg, 2005).

The role of local and national actors is to encourage local participation, to support the implementation, and to monitor certification activities. They also develop and test regional standards (Cadman, 2011). Bringing a national perspective to standardization and certification activities is important.

Standardization Process

The development of standards includes next phases (Cadman, 2011):

- Initiation (requesting standards and setting up committees, staff, and working groups).

Forest Stewardship Council, Table 2 Principles for forest stewardship (FSC, 2004, p. 15)

Principles	
1. Compliance with laws and FSC principles	“Forest management shall respect all applicable laws of the country in which they occur, and international treaties and agreements to which the country is a signatory, and comply with all FSC Principles and Criteria”
2. Tenure and use rights and responsibilities	“Long-term tenure and use rights to the land and forest resources shall be clearly defined, documented and legally established”
3. Indigenous peoples’ rights	“The legal and customary rights of indigenous peoples to own, use and manage their lands, territories, and resources shall be recognized and respected”
4. Community relations and workers’ rights	“Forest management operations shall maintain or enhance the long-term social and economic well-being of forest workers and local communities”
5. Benefits from the forest	“Forest management operations shall encourage the efficient use of the forest’s multiple products and services to ensure economic viability and a wide range of environmental and social benefits”
6. Environmental impact	“Forest management shall conserve biological diversity and its associated values, water resources, soils, and unique and fragile ecosystems and landscapes, and, by so doing, maintain the ecological functions and the integrity of the forest”
7. Management plan	“A management plan – appropriate to the scale and intensity of the operations – shall be written, implemented, and kept up to date. The long term objectives of management, and the means of achieving them, shall be clearly stated”
8. Monitoring and assessment	“Monitoring shall be conducted – appropriate to the scale and intensity of forest management – to assess the condition of the forest, yields of forest products, chain of custody, management activities and their social and environmental impacts”
9. Maintenance of high conservation value forests	“Management activities in high conservation value forests shall maintain or enhance the attributes which define such forests. Decisions regarding high conservation value forests shall always be considered in the context of a precautionary approach”
10. Plantations	“Plantations shall be planned and managed in accordance with Principles and Criteria 1–9, and Principle 10 and its Criteria. While plantations can provide an array of social and economic benefits, and can contribute to satisfying the world’s needs for forest products, they should complement the management of, reduce pressures on, and promote the restoration and conservation of natural forests”

- Development (public consultation, drafting, testing, resolution (disputes and adoption)).
- Implementation (publication, review, and revision).

National working groups are responsible for developing national standards with the aim of finding locally effective solutions. However, solutions must comply with the FSC principles and criteria before they can be approved. The certification process begins at the request of the forest owner or forest manager. The basis for the assessment is an approved national standard, if one exists. In the absence of a national standard, the certifier will use their own standard, which should be in line with recent decisions of the General Assembly (Cadman, 2011).

The standards produced by the FSC are:

- The global forest management standards, which form the basis for the development of national and regional standards.
- The custody standards to define rules in the production chain.
- The standards for the accreditation of independent certifiers.

All standards are developed by the Standards and Policies Unit of the International Secretariat and approved by the director board. The standard-setting process includes also negotiations with stakeholders (Pattberg, 2005).

Another important thing in private regulation is implementation, which includes

Forest Stewardship Council,
Fig. 3 Institutional organization of the FSC. (Cadman, 2011; Pattberg, 2005)

certification, accreditation, and labeling. The FSC certification has used for other interventions as an example of responsible management of renewable resources (Chaplin-Kramer et al., 2015). The certification process confirms that the agreed basic management or output standards have been met. Accreditation refers to the process of accrediting the certifying organizations based on some general rule. Labeling refers to the process and practice that allows the label to be affixed to products or production chains.

The forest owner can be issued a certificate if the forest management has complied with the FSC forest management standards. On the

basis of this certificate, they can market their products as certified wood and use the FSC logo. A chain of custody certificate, on the other hand, is issued for the labeling of wood products. It includes the phases of wood processing, wholesale and retail. It can be granted for the labeling of wood products if certified and non-certified wood are not intertwined (Pattberg, 2005).

Pros and Cons of FSC’s Forest Certification Schemes

For years, the FSC had a monopoly on forest certification. Since the beginning of the

millennium, there has been international competition in the sector (FAO, 2005). Debate still exists about the merits of forest certification schemes. The evaluation of certification schemes should take into account positive and negative, direct and indirect, short- and long-term, as well as intentional and unintended effects (OECD, 2002).

In general, the FSC certification process is considered successful (Pattberg, 2005). This is evidenced by the support given to it by environmental associations and public organizations. The FSC certification influences the debate on sustainable forestry as well as national forest policy through various mechanisms. In addition to standardization, the FSC also contributes by supporting the finding of solutions to environmental problems and the dissemination of information to stakeholders, as well as by providing a learning environment not only for the FSC members but also for independent organizations. These mechanisms support international approaches to implementing sustainable development by creating and maintaining a new kind of institutionalism among private actors (Pattberg, 2005).

Moore et al. (2012) have shown that social and community actions were developed in the FSC-certified organizations. This was reflected, for example, in the increase in preparation of forest management plans, implementation of forest inventory programs, establishment of spatial information systems, control of exotic invasives, chemical safety monitoring, and biodiversity. Also public consultations and program reports as well as expansion of public relations and information were increased. This finding is also supported by the results of Cerutti et al. (2014) showing that FSC-certified concessions enable more active and effective negotiations between the local population and the logging company. Cerutti et al. also noticed that FSC-certified forest management units were found to provide better housing and living conditions, health insurance, and access to medical facilities for workers and also to encourage benefit-sharing mechanisms and a more equitable redistribution of profits to local communities. In addition, Moore et al. (2012) found that

environmental system chain-of-custody tracking, internal program monitoring, natural heritage planning, management review systems, and commitment to continuous improvement were increased. Van Kuijk et al. (2009), in their part, have shown that well-managed production forests, including FSC-certified forests, have more species-friendly effects than conventionally logged forests. In the light of the examples described above, it appears that FSC certification prompted improved environmentally, socially, economically, and sustainable forest management.

Masters et al. (2010) and Moore et al. (2012) argue that forest certification is a robust approach to promoting the social and economic sustainability of forests. Moore et al. (2012) state that there are differences both between certifiers, in the regional standards, and in the implementation of the FSC standards. In line with the certification principle of continuous improvement, the FSC standard is focused on management systems and internal records. Most FSC changes were made in the environmental/forest management component. Almost as much, there were economic/systemic changes and social/legal changes. The most frequent environmental changes concerned new forest management plans, old-growth reserves, and forest inventory programs. The custody chain, the publication of the forest plan, stakeholder meetings, and community consultation also changed frequently as a result of the FSC (Moore et al., 2012). In the new global strategy, the FSC reports that it will develop new approaches, taking into account the value of forests and the benefits of forest management so that society can accept these approaches (FSC, 2021).

The FSC has been criticized since its establishment. The legitimacy of the FSC has been questioned both nationally and internationally. In the FSC, stakeholder groups negotiate a legitimate authority over the use of forest resources (Eden & Bear, 2010), so the FSC lacks democratic legitimacy (Cashore, 2002). The most well-known critic of the FSC from major international organizations has been Greenpeace. It has critically assessed the FSC's performance and made recommendations to improve the organization's credibility. For example, Greenpeace has stated that

there is a lack of guidance by FSC on High Conservation Value Forest interpretation and implementation and guidance on “High-Risk” situation concerning, e.g., Congo Basin (Greenpeace, 2010). In 2018, Greenpeace did not renew its FSC membership (Greenpeace, 2018). Also according to Korteland (2007), there are many problems in FSC certification concerning environmental impact as overall trade impact, marginal environmental impact, and poverty impact concerning trade and social impacts in developing countries (Table 3).

In its new target program, the FST seeks to respond to the criticisms it has received. It tells to develop solutions “to help halt deforestation, grow the world’s forest area and improve its quality, including forest conservation as well as restoration of degraded or converted areas to more natural conditions” (FSC, 2021, p. 10). In these

ways, the FSC seeks to meet global challenges and the goals of the UN Sustainable Development and the Paris Agreement. Reconciling forest protection and economic exploitation is not easy. It may succeed under favorable conditions through careful planning based on the environmental, social, and economic sustainability pillars of the triple bottom line.

Summary

The Forest Stewardship Council (FSC) is a member organization of individuals and communities operating at the national and international levels. Environmental organizations, indigenous interest groups, trade unions, foresters, and large retailers established it to create and implement forest management guidelines and rules in 1993. In the standardization process it has developed, the FSC has sought to combine ethical views related to the environment with social and business principles. The organization is led by the General Assembly (GA), which has three chambers (economic, social, and environmental). The GA elects a director board to which each chamber sends three members. The FSC’s operational work is the responsibility of an international secretariat under the supervision of the executive director appointed by and responsible to the director board. The FSC’s work is based on the internationally agreed principles and criteria which define which practices are considered “environmentally appropriate, socially beneficial and economically viable management of the world’s forests.” Over the years, FSC has supported the activities of its stakeholders nationally and globally through responsible forest management standards. If the forest management is found to comply with the FSC forest management standards, the landowner will be issued a certificate entitling them to market their products as certified wood and use the FSC logo. Despite many good achievements, the FSC has been criticized since its establishment. For example, the legitimacy of the FSC has been questioned, and its policies and activities have been criticized.

Forest Stewardship Council, Table 3 Impact-based critiques (Korteland, 2007)

Impact type	Critiques
1. Environmental impact Overall trade impact	Certification is limited on a global scale: both demand and supply are geographically skewed toward northern countries
2. Marginal environmental impact	There is a lack of quantitative evidence revealing that compliance with the FSC standards on which certification is based actually improves forest management The FSC uses vague conditions in their certification process The effectiveness of the criteria an sich to improve environmental quality is questionable FSC’s actual impact in a global sense seems to be limited what concerns on environmental problems
3. Poverty impact	
Trade impact developing countries	There is no evidence that labeling acts as a barrier to trade for less developed countries
Social issues	Especially less-resource groups lack access to the FSC label

Introduction

Forum Ethibel aims to help companies sustain an energetic balance between economic progress, environmental protection, and social responsibility. Ethibel-labeled investment funds hold shares in companies listed in their Register. The amalgamation of data on sectors, firms, and ESG (i.e., Environmental-Social Factors-Good Governance) with their appraisal by a panel of experts known as the Register Committee helps create the Investment Register of the company.

Anchors of Forum Ethibel

The first anchor of Forum Ethibel is “Trendsetter,” which explicates its values and vision on sustainability by examining quantitative data. The second anchor, “Investment Register,” maintains a roster of firms and nations to which the Forum Ethibel filters have been applied. The Register seeks to

maintain a balanced sectoral and geographical spread so as to enable fund managers to build financially and technically balanced portfolios.

The Register uses a funnel approach by first collecting data about firms, sectors, and ESG scores from Moody’s ESG Solutions. The Register has firms and nations chosen based on financially and technically sound portfolios as reflected by their annual reports, websites, and additional information from other stakeholders such as trade unions and environmental organizations.

The next step is to use a “sustainability filter” that has both positive and negative components. For firms, the positive considerations include having solid and ambitious policies, effective utilization of resources, and evidence of assessable results. The avoidable components include no involvement in arms, gambling, nuclear-powered energy, or tobacco, while for nations, they must not be involved in conflict, war, or serious crisis situations and not be violating labor laws or human rights. For nations, the metrics include how well they protect the environment, follow the rule of law, and are committed to social protection and solidarity.

Rating Criteria

Each firm receives a score based on a reflection of how well they have performed with respect to their competitors in the same sector. The strong scores range between A, B, or C. Those that are outstandingly strong or innovative are labeled as Pioneers (A), those with the best scores within their sectors, labeled as Best in Class (B), while those with above sector average get a “C.” A “D” is assigned to those below sector average, an “E” to those far below average and/or not transparent, while those firms engaged in armaments, gambling, nuclear energy, or tobacco are rated “M.” Those rated as A, B, or C are automatically included in the Investment Register, while those receiving ratings of D, E, or M are excluded.

The Investment Register is a dynamic entity updated six times yearly – every sector is assessed biennially. Not only is the current status of the firm assessed, but also their future potential

Forum Ethibel Sustainability Index, Fig. 1 The two labels issued by Forum Ethibel. (Source: <https://www.forumethibel.org/>)

F

evolution. They are notified of their evaluations and whether or not they were added or excluded from the Register. The decisions based on the appraisals are always broadcast to the public after informing each firm.

Labels and Certificates

Forum Ethibel offers two labels (Fig. 1) based on sustainable investment practices: Ethibel PIONEER (scores of A or B) and Ethibel EXCELLENCE (scores of A, B, or C).

Labels are issued under stringent conditions outlined in a contract. Forum Ethibel regularly checks to see whether firms are meeting the terms of the agreement. The funds also include government bonds and those issued by international institutions; the labels do not indicate the “financial quality” of a fund, such as their expected return or risk profile.

Forum Ethibel also grants certificates (Fig. 2) to validate that a product or service is in compliance with corporate social responsibility (CSR) conditions. Certificates are typically issued for short periods, ranging from one trimester to a year, and periodic audits are carried out to ensure that the client continues to meet the benchmarks. Certificates are given for a wide range of products,

Forum Ethibel Sustainability Index, Fig. 2 Certificate Issued by Forum Ethibel. (Source: <https://www.forumethibel.org/>)

such as reinvestments in socio-ethical programs, verification of carbon reduction programs, and solidarity and impact investments.

Background

The nonprofit sector is characterized by a great diversity of activities, organizations, and institutions (Anheier 2022). Especially, charitable foundations are well-known social institutions in the third sector due to their philanthropic projects (e.g., Rockefeller Foundation, Bill and Melinda Gates Foundation, and Nobel Foundation). The history of foundations dates back thousands of years: Some researchers traced back the origins of foundations to the library of Alexandria (Coon 1938). These early forms operated locally with a limited amount of assets used for grantmaking. In the Middle Ages, the Christian church took over an important role in the increasing value of foundations. In the Islamic world, *waqfs* are known as an equivalent to foundations (Kiger 2022; Ali and Oseni 2021).

The growth of foundations over the recent decades depends on many contextual factors. Therefore, countries around the world face quite different experiences with the roles performed by this special social institution: While in the early twentieth century, American foundations had an important leadership part, European countries experienced a foundation boom in the last two decades of the twentieth century (Anheier 2022). Since the national institutional framework differs broadly for foundations around the world, cross-national data on foundations is difficult to access (Toepler 2018; Salamon and Anheier 1993). However, a consistent rise in the total number of foundations is observed in many countries (Anheier et al. 2018; Anheier 2022). In Germany,

for example, the number of foundations established according to civil law increased from 10,503 in 2001 to 23,876 in 2020, but the yearly growth rate dropped slightly from 7% in 2001 to 3% in 2020 (see Fig. 1).

Definition and Perspectives on Foundations

Although the importance of foundations is growing globally, research on foundations is still at an early stage (Toepler 2018; Anheier 2022) and was dominated by works on US foundations for a long time (Jung 2020; Adloff 2015). Consequently, the definition of these traditional institutions remains opaque (Toepler 2018). For some researchers, foundations remain “black boxes” (Bethmann et al. 2014). In contrast to membership-organized associations, foundations are institutions without owners and members. They offer an institutional framework for a long-term commitment to different projects and perform functions of an intermediary. Hence, the important internal governance mechanism provided by ownership rights is malfunctioning. Moreover, external governance mechanisms are lacking as well since foundations typically are not left to market discipline.

Using structural and operational features (Anheier et al. 2017; Salamon and Anheier 1992), a stylized foundation is characterized by five elements (see Fig. 2):

- (1) Founder oriented: Over its life cycle, a foundation is a persistent expression of the charismatic intentions of the founder (Adloff 2015).
- (2) Asset-based: The longevity characteristic of foundations is achieved by the transfer of proprietorship of assets from the donor to the institution. The assets are the base to success and failure of foundations (Anheier and Leat 2018).
- (3) Self-governed: In addition to the transfer of assets, the donor usually must file a charter when incorporating a foundation. Basically, the charter defines the purpose and the institutions of the foundation. Although foundations are often well known for charitable purposes, other purposes can be pursued as well (Anheier 2022). Furthermore, the charter is set up to offer guidance to the board of directors that is responsible for the management of the transferred assets. However, other issues can be regulated in the charter as well.
- (4) Non-profit distributing: Income generated from asset management is not distributed to

Foundations, Fig. 1 Foundations in Germany from 2001 to 2020. (Source: own figure based on data from Bundesverband Deutscher Stiftungen 2021)

Foundations, Fig. 2 Stylized definition of a foundation. (Source: own figure)

shareholders but paid out to the beneficiaries. Asset management follows the purpose/mision of the foundation codified in the charter (Fritz and von Schnurbein 2015; Toepler 2004).

- (5) Supervised: In compensation for the missing ownership rights, the management of foundations is monitored and controlled by authorities. Typically, foundations are asked to present financial and nonfinancial reports. This is the base for checking the accountability of foundations (Carolei 2022).

Theoretical research on foundations is scattered across different disciplines and is advancing slowly (Jung 2020). Research in law focuses on comparative law on foundations' governance (Thomsen 2014; Hopt et al. 2009) and addresses the regulation on foundations (Toepler and Abramson 2021; Hopt et al. 2009). Besides, some parts of the literature analyze tax-related issues (Seer 2021; Hopkins 2016).

Economic analysis of foundations can be structured by referring to the structural and operational definition proposed above (see Fig. 2). First, accepted agency-theory for institutions offers guidance for the analysis of foundations as well (Jensen and Meckling 1976). Accordingly, the board of management is acting as an agent on

behalf of the founder and the beneficiaries (principals). The corresponding general information risk, the hidden information risk due to asymmetric information between principal and agent, and agency risks resulting from the delegation of decision-making authority offer starting points for a detailed economic analysis (Kaufman 2021). However, the strong assumptions in agency-theory neglect nonfinancial utility or emotions of the founders that is an important context factor for setting up a foundation. Therefore, drawing on the socio-emotional wealth theory (Gómez-Mejía and Herrero 2021; Zellweger and Astrachan 2008) grounded in prospect theory can offer a second research avenue for the analysis of foundations (Kaufman 2021). In addition, management literature addresses stakeholder approaches (Stahl 2014). Other parts of theoretical economic literature emphasize the role foundations perform in supporting social innovations by referring to behavior-based organizational theories (Bethmann 2019; Jaskyte et al. 2018; Bethmann 2014; Heutel and Zeckhauser 2014). Besides, the challenges resulting from the asset-based characteristic offer research avenues in corporate finance-related research (Kremer and Achleitner 2022; Kaufman 2021; Anheier and Leat 2018).

Finally, research in social science addresses the role and advantages of foundations, as well as

policy recommendations on the regulatory framework (Anheier et al. 2019; Toepler 2018; von Reeden 2015).

Regulatory Framework for Foundations

Beyond the sketched stylized governance structure, a great variety of foundation forms can be observed around the world (Anheier 2018; Hopt et al. 2009). In some parts of the world, foundations are low regulated because of their character as self-organized institutions that emerged to balance conflicts between private and public interests. In contrast, foundations in other countries operate in a highly regulated environment or sometimes even are not allowed at all (Toepler 2018). This regulatory response addresses the lack of governance mechanisms linked to the transfer of property rights and provides a legal definition of foundations as well (Toepler 1998).

Especially in Europe, the legal framework for foundations is expressing different policy approaches and cultural factors. Therefore, as part of the general revision of corporate law, the European Union (EU) in 2012 presented a proposal for a European Foundation Statute (EFS). This new European legal form (Fundatio Europaea) was supposed to increase foundations' cooperation across EU member states and to facilitate cross-border tax law treatment (Breen 2014). Although promoted broadly by many researchers and foundation umbrella organizations, the proposal was not negotiated successfully. In the end, the UK, the Netherlands, Denmark, Austria, and Slovakia rejected the EFS initiative by using their veto rights (Breen 2015).

Based on the stylized structure presented above, some primal elements can be derived for the set-up of a regulatory framework for foundations (see Table 1). In line with the five characteristics of the foundation phenomenon, five main fields of regulation are typically addressed in the regulatory framework for foundations. This conceptual framework can be used by policy makers to reflect on the current foundation law critically and to develop a more rational regulatory framework (Markworth 2021; Hopt et al. 2009).

Foundations, Table 1 Basic regulatory framework for foundations (source: own figure)

Conceptional criteria of foundations	Basic elements for the regulatory framework
Founder	Rights Taxation
Asset-based entity	Legal personality Formation Purpose and statutes Liquidation Taxation
Foundation self-governance	Board of directors Other organs Activities
Beneficiaries	Rights Taxation
Supervision	State supervisory authority Public register Information and inquiries Approval of fundamental decisions Enforcement measures Reporting, disclosure, auditing

Moreover, the key features of the framework can be used by researchers for a comparative cross-country comparison of foundation ecosystems (Philanthropy Advocacy 2021; Anheier and Toepler 1999; Toepler 1998).

Empirical Evidence of Foundations

Corresponding to the range of introduced regulatory issues, many different types of foundations exist in real life (Table 2). Furthermore, since many context factors influence the ecosystem of foundations and foundation law, comparable data for a cross-national analysis of the empirical evidence of foundations is difficult to obtain (Anheier 2022). Thus, current research on foundations refers to qualitative research approaches and mainly focuses on developed countries (Giacomin and Jones 2021).

The classification of foundations can refer to legal, socio-economic, and other criteria (see Table 2). For legal explorations into the nature of foundations, the first four criteria are crucial (Kaufman 2021): According to the basic legal

Foundations, Table 2 Basic types of foundations (source: own figure)

Criteria (non-conclusive)		Type of foundation		
Legal	Legal framework	Civil law	Public law	Case law
	Regulator	Self-regulated	State-regulated	
	Establishment	Dedication	In case of death	
	Taxation	Taxable	Tax-exempt	
Socio-economic	Donor	Individual	Legal entity	
			Private	Public
	Purpose	Charity	Non-charity	
	Business model	Operating	Financial	
	Field of activities	Economic	Non-economic	
			Social	Other
	Term	Infinite	Finite	

framework, foundations can be formed by civic, public, and case law (see Table 2). The regulatory framework that must be considered for the formation of a foundation can be set by different regulators (see Table 2). Based on the way of establishment, foundations are formed by dedication or in case of death. Finally, foundations can be taxable or tax-exempt. In contrast, the socio-economic analysis of foundations mainly refers to five other criteria: According to the criterion of the donor, foundations can be private or public. Moreover, the distinction based on the purpose pursued by the foundation leads to the classification of charity (philanthropic) and non-charity foundations. The business model adopted by a foundation can be operational. Likewise, foundations can act as financial intermediaries by making grants generated by asset portfolio management. Using the field of activities as a criterion leads to the classification between economic and non-economic foundations (see Table 2). Finally, the term of a foundation can be infinite or finite (see Table 2).

Charitable foundations which emerged around the world at the turn of the nineteenth century are the best-known foundation type in real life. Typically, these foundations were set up by individuals, focus on charity purposes communicated in the statutes, and typically display activities in non-economic areas (Table 2). While this type of foundation originally operated own business (e.g., hospitals, schools, and universities), today these institutions focus on grantmaking activities based

on the income generated from asset portfolio management respecting the purpose of the founder (Jung 2020). Since societal challenges outweigh other foundation purposes, investment concepts in line with the United Nations Sustainable Development Goals (SDGs) are becoming more and more important for the investment policy of foundations (Kremer and Achleitner 2022). This voluntary set of investment principles offers guidance to plausible actions for incorporating environmental, social, and governance (ESG) factors into investment practice (Stühlinger 2018; Tizian and von Schnurbein 2015). In addition to the establishment by individual persons, many foundations are set up nowadays by a legal entity (see Table 2). Accordingly, corporate foundations and public foundations are further manifestations in real life. In Germany, for example, in March 2021, 31% of the foundation population was set up by legal entities (see Fig. 3). The predominant type within, the corporate foundation, is characterized by three criteria: First, it is a separate legal entity operating separately from parent company; second, it is operating for a charity purpose and not for economic reasons; third, it is funded and controlled by a for-profit entity (Roza et al. 2020). In line with the increasing number of corporate foundations, researchers from different fields are becoming increasingly interested in this type of foundation (Gehring 2021; Roza et al. 2020; Bethmann and von Schnurbein 2015).

Private and corporate charitable foundations as legal entities compete with other legal forms

(Toepler 2019). Depending on the specified purpose, the benchmark can be a not-for-profit corporation, an association, or a charity trust. In recent years, different governments around the world made a lot of efforts to introduce new legal forms: For example, in the USA, Italy, and France benefit corporations were already regulated (Colinveaux 2022; Ferrarini and Zhu 2021). In Germany, the benefit corporation is currently undergoing the legislative process, additionally reforms on foundation law are initiated (Markworth 2021; Weitemeyer 2020; von Oertzen 2019).

Foundations, Fig. 3 Donors of German foundation in March 2021. (Source: own figure based on data from Bundesverband Deutscher Stiftungen 2021)

Because of the longevity focus and their openness to customized design, industrial foundations, or foundation-owned firms (FoF) are another prominent type of foundation (Stiftung Familienunternehmen 2021; Schienke 2018; Thomsen and Rose 2004.). Industrial foundations are autonomous nonprofit entities that own a majority interest in one or more conventional business firms (Block et al. (2020); Thomsen and Rose 2004). Industrial foundations can perform the role of a majority shareholder (see Fig. 4, left side). Accordingly, economic analysis can be based on the existing research on blockholder ownership (Achleitner et al. 2020). Type A is the simplest construction of an industrial foundation where the foundation owns 100% of the corporation. Type B is offering a customized solution by referring to two foundations, a family foundation and a charity foundation, as the owner of the company. This construction allows a separation of ownership and voting rights and takes into consideration tax challenges. With Type C the corporation is owned by a combination of foundation and family business. In contrast to these three types, foundation can become a minority shareholder as well (see Fig. 4, right side). Accordingly, other private and/or institutional investors take over control of corporate basic

Foundations, Fig. 4 Basic types of industrial foundations. (Source: own figure; based on Fleisch 2018)

decisions. Type D can be combined with Type B and Type C on the left side.

Very often the foundation is set up by the company founder, and the founder's family sometimes continues to have influence on management decisions by using customized models (see Fig. 4, left). Accordingly, the prevention of family conflicts is one key factor in the explanation of FoF (Kaufman 2021). At present, industrial foundations are a phenomenon in Northern Europe and sometimes include well-known multinational global players: for example, Aldi (Germany), Ikea (Sweden), Bertelsmann (Germany), Heineken (Netherlands), and Carl Zeiss (Germany). Previously, this type of foundation was also common in the USA until the Tax Reform Act of 1968 which prohibited FoF. Although the interdiction was reversed in 2018, industrial foundations did not recover in the USA (Hansmann and Thomsen 2021). Accordingly, tax law is a key factor in encouraging industrial foundations as well (Fleisch 2018). However, the lack of ownership and missing information on the foundation's governance internal structure result in a lack of transparency (Achleitner et al. 2020). Currently, the potential of FoF in overcoming short-termism and contrasting short-term profitably is discussed in economic research (Thomsen et al. 2018). Therefore, industrial foundations are supposed to play a significant role in addressing sustainable development goals and transforming the financial system to be more sustainable (Stühlinger 2018).

Term and Definition

The term “fraud” has at least two different meanings, of which one is referring to a certain way of

acting, the second to a person who acts accordingly.

This entry deals with the activity related meaning which again has to be differentiated and may be defined as follows:

1. An intentional deception, that is, the perversion of truth, practiced in order to induce another to give up something of value, in most cases the possession of property, or to surrender a (legal) right
2. The act of deceiving, misrepresenting, or cheating, also known as “trick” or a piece of “trickery,” with the aim of gaining an unfair advantage (See e.g. Merriam Webster Dictionary).

In a business-related context, intentional fraud is a severe criminal offence. The US American Association of Fraud Examiners (ACFE) (ACFE: Report to the Nations – 2018 Global Study on Occupational Fraud and Abuse 2018) distinguishes between three primary categories of fraud, listed below in the order of their frequency of occurrence:

- Asset misappropriation
- Corruption
- Financial statement fraud (ACFE 2018, p 10).

Fraud in this definition, thus, is used as an overall concept for morally wrong, harming, and mostly criminal behavior in a corporate and business context.

Categories of Fraudulent Behavior in a Corporate Context

For illustrating the different types of fraudulent behavior, the so-called *fraud tree* is often used in literature (Grüninger 2020, p 43). In its 2018 report to the Nations, the ACFE calls this tree *Occupational Fraud and Abuse Classification System* (ACFE 2018, p 11). Following this classification, the first branch – corruption – is subdivided into conflicts of interest, bribery, granting undue advantages, and economic extortion, whereas the second branch – asset

misappropriation – is differentiated into financial and other property damages, including theft and fraudulent disbursements on the one hand, respectively misuse and larceny on the other hand. The third branch deals with the manipulation of financial statements, distinguishing, for example, between net worth respectively net income overstatements and understatements. Fraudulent behavior belonging to this branch of the fraud tree may include, for instance, wrong period end accrual, fictitious or understated revenues, as well as improper asset valuations and disclosures (Fig. 1).

From the perspective of preventing fraud, this classification should be further divided into the categories of *fraud against the company* and *corporate misconduct* (Grüniger 2020, p 45). The former is relating to those types of criminal behavior which are damaging the company itself, corresponding in the fraud tree mainly to the branch of asset misappropriation; the latter is including forms of criminal activities which, at least in the short run, lead to advantages for the company such as corruption and financial statement fraud. In order to prevent these types of

F

Fraud Prevention and Detection, Fig. 1 Occupational fraud and abuse classification system (the Fraud Tree). (Figure taken from the ACFE report, ACFE 2018, p. 11)

fraud effectively, different approaches and instruments have to be applied: Whereas the risk that fraud against the company takes place may be mitigated by thorough internal and external control mechanisms, the avoidance of corporate misconduct requires a more encompassing approach, for example, in the form of a values based compliance and integrity management, focusing on the development of a corporate and leadership culture that support ethical behavior and integrity (Grüninger 2020, p 46; see also below).

Reasons and Preconditions of Fraudulent Behavior: The Fraud Triangle

The underlying assumptions of anti-fraud-management have been illustrated for the first time in the late 1940ies by Donald R. Cressey, a pioneer in the area of business criminology, in the form of the so-called *fraud triangle*. In the context of a survey among 200 business criminals, Cressey analyzed the preconditions under which individuals commit a crime in a corporate context, in particular fraud (See e.g. Wells 2014). The outcome of his study was that at least three factors have to coincide, that is, take place at the same time, namely

1. A subjectively felt pressure – which Cressey mainly explained with financial needs, whereas later research revealed as main motives external pressure to reach certain goals and targets of the company
2. A subjectively felt “good” opportunity, often based on the (insider) knowledge of the potential offender about internal processes, control mechanisms, etc. and how they can be successfully avoided
3. A personal justification in the form of a self-convincing moral rationalization and excuse of the planned action (e.g., “this is s.th. the company owes to me,” “it is only fair if I take this in return”) (Wells 2014, p 36).

To burst at least one of the three sides of the triangle was considered as key for preventing

fraud. For being the best influenceable factor by an organization, the second aspect was regarded as the most appropriate one. Prevention of fraud, thus, should focus on clearly indicating to potential offenders that due to effective (internal) control mechanisms the chances to successfully commit a crime are very low.

Later surveys, however, for example, by the German criminologist Kai D. Bussmann in collaboration with PriceWaterhouseCoopers (Bussmann 2004, 2009), showed that one of the strongest factors of countering fraudulent behavior is the self-binding and commitment of individuals to moral values such as honesty and integrity. It could be proven that in the situation of potentially using an opportunity to commit fraud, before rational reflection – for example, about the probability that the wrong behavior will be detected or about the gravity of punishment in case of detection – even starts, something else comes into effect: the so-called *value filter* (Bussmann 2004, p 37; Kleinfeld 2020, p 766).

Effective anti-fraud-management of and in organizations, therefore, has to be embedded into a management of and by values which had been promoted already in the 1990ies in the context of the Business Ethics debate in the United States and in Europe (Wieland 2020, pp. 31–33; Kleinfeld, dito).

Prevention and Detection of Fraud

In general, anti-fraud-management consists of three main tasks:

- Fraud auditing
- Fraud prevention
- Fraud detection (Wells 2014, p 24).

The first area, *fraud auditing*, is often supported by external accountants and covers the analysis of units, departments, sectors, general and specific corporate processes, etc., which are considered to be fraught with risk. In the case of detected fraudulent activities, this may include the elucidation and the refurbishment of incidents, the investigation, and repatriation of damages as well

as a critical examination of the existing internal control mechanisms.

In the context of the next step, the *fraud prevention*, solutions, and instruments to guard an organization against all kinds of fraud and to minimize existing or potential risks of becoming a victim of fraudulent behavior have to be identified, developed, and implemented. As mentioned above, different kinds of fraud require different methods of prevention: Against financial or other forms of material damages resulting from fraud types such as deception or misappropriation which can be summarized under the category of *fraud against the company*, an internal control system which is state of the art may be rather helpful and successful (Grüninger 2020, p 46). In constellations where the motivation of fraudsters is not as clearly driven by personal interests or simply by criminal energy; however, a more systemic approach of prevention is needed, including the identification of organizationally induced reasons and motives of fraudulent behavior such as unwritten rules being transported by the existing corporate culture, explicit or implicit incentive mechanisms, pressure to succeed, etc. The prevention of fraud belonging to this category of *corporate misconduct*, as Grüninger names it, needs an equally complex and holistic answer.

Fraud detection, finally, deals with the important process of systematically identifying risks of fraudulent behavior as well as potential indicators for it, so called red flags, often carried out in the form of internal or external detection audits. In the case of concrete suspicion, usually external auditors are asked to investigate. In specific cases of potential criminal behavior such as money laundering, computer-based forensic investigation instruments are used. In the meantime, the majority of examinations to detect fraud activities are at least IT-assisted (See e.g. Grüninger 2020, p 62). An important role in the detection of fraud also play *whistleblowing systems* – in the form of either external ombudspersons or of sophisticated digital solutions – who are able to guarantee the protection of the anonymity of the informer while being in dialogue with him or her. The latter is an

important factor to check the plausibility of a received tip whereas maintaining the anonymity of a whistleblower in the majority of cases is the prerequisite for him or her to speak up at all, in the first place because of impending reprisals (Tur 2020, pp. 875–878).

One of the first frameworks which defined clear standards for effective prevention of fraud and other forms of criminal behavior were the US Sentencing Commission Guidelines, in its first version published in 1991 (US Sentencing Commission 2018). They added to the classical anti-fraud-management scheme described above another dimension: the need of appropriately *responding* to criminal behavior by the company (Grüninger 2020, p 61). Next to investigating and analyzing the reasons for the detected fraud, this includes a systematic fraud reporting and, most importantly, to consequently sanction all kinds of fraudulent behavior independent from the hierarchy level where it took place. This is not only important for the internal and external credibility but also for the preventive effect and improvement of anti-fraud-measures. Prevention, detection, and an appropriate reaction to fraud, thus, are forming an important, interdependent circle and have become a minimum requirement of corporate programs in the area of anti-fraud and compliance management (Grüninger 2020, pp. 61–62).

Effective Fraud Prevention: Compliance and Integrity Management

Another important step on the path to effective anti-fraud-management was the publication of the Sarbanes Oxley Act (SOX) in 2002, again by the United States as a reaction to the spectacular “cooking the books” – scandals around the companies Enron and WorldCom – only topped, perhaps, by the recent scandal at the German company WIRECARD. The new law made compliance and compliance management mandatory for all companies worldwide if they want to be listed at any stock exchange located in the United States. Until then, in Europe, only the financial

sector had heard of and practiced “compliance” in a corporate context (Kleinfeld, Martens 2018, p 6).

Compliance in the definition of the SOX and other frameworks at that time were based on a narrow understanding, equating it with legal and rule conformity being achieved mainly by measures of control and deterrence. This started to change with the 2004-version of the US Sentencing Commission Guidelines which recommended to embed all corporate measures to prevent and fight criminal activities in a holistic “compliance and ethics program.” Apart from preventing and detecting criminal conduct, an “organizational culture” should be promoted that “encourages ethical conduct and a commitment to compliance with the law” (Wieland, p 20; US Sentencing Commission, Guidelines, § B2.1). In 2010, a similar passage was taken up in the UK Bribery Act (UK Bribery Act 2010, principle 2).

This new and much broader understanding of compliance and compliance management reflected a debate which had already taken place in the 1990ies in the context of the young discipline of Business Ethics in the USA and in Europe. It was dealing with the question whether (legal) compliance could be considered as a minimum requirement of corporate ethical behavior, or not. Starting point of the controversial discussion was the hypothesis that a so-called integrity approach (See e.g. De George 1993, Paine 1994, Becker 1998), based on a positive idea of the human being, on a management of and by values, on the conscious development of corporate culture, as well as on the intrinsic motivation and commitment of the organizational members (Kleinfeld 2020, pp. 764–766), would be significantly more effective than a pure compliance approach, concentrating on controlling and sanction mechanisms only (Kleinfeld and Martens 2018, p 7; Schöttl 2018, pp. 38–41). This assumption, among others, was backed by the research of criminologists, as mentioned above, and today may be considered as a widespread position, held at least by experts in the field (Wieland 2020; Grüninger 2020; Kleinfeld 2020).

A European example for a guidance standard based on the integrity approach has been

developed by the Centre for Business Ethics (ZfW), the research institute of the German Business Ethics Network – EBEN Germany, in the late 1990ies already. The certifiable standard ValuesManagementSystem, (ZfW 1998) which established itself in some “sensitive” sectors such as the construction industry, describes the necessary elements and steps for creating a management system which is able to effectively prevent fraud by developing an integrity fostering corporate culture in the context of a values based compliance management. The four main processing levels of the guidance document include:

1. The *codification* of normative orientations in the form of core values, principles based on the ethical commitment and the self-image of an organization and their translation into more concrete guidelines, policies and procedures
2. The *implementation* by integrating these normative orientations into the formal and informal corporate governance mechanisms, such as the strategic decision-making, into operational processes, daily routines and procedures, incentive systems, etc., as well as into all functional management areas (HR, sales, purchasing, etc.). The implementation process should be accompanied by appropriate communication, training, and personnel development measures with a clear focus on management and leadership style
3. The *systemization* by developing a continuous implementation and improvement process, in the first place by combining it with already existing management instruments or management systems, for example, in the area of quality, risk, environmental, or CSR management, which are appropriate for the size and complexity of the organization. This step includes the establishment of regular internal controlling, monitoring, reporting, and auditing activities as well as internal speak-up or whistleblowing instruments
4. The *organization* of the values based compliance management which, above all, had to make clear to all internal and external stakeholders of the organization that the main responsibility for compliance, integrity, and

the implementation of the existing normative orientations lie on the side of the (top-) management, whereas operational functions only support it

Bulgaria

Synonyms

Group of twenty; New group of twenty

Definition/Description

The Group of Twenty (G20) is an international intergovernmental forum, made up of 19 countries and the European Union, which represents the world’s major developed and emerging economies. The G20 members together represent 73% of global GDP (Statista 2021), 80% of international trade (EC 2021), and two-thirds of the world’s population (World Population Review 2021). Because the forum brings together the countries considered to be of systemic importance to the global economic and social order, it is considered to be one of the most influential regular international events that have a significant role in setting the paths for future economic growth and ensuring stability of global markets (Kirton 2015).

The first G20 forum was conducted in 1999 as a meeting of finance ministers and central bank governors of the 19 + 1 members. For the first 10 years of its existence, the forum continued to

be a meeting on ministerial level. In 2008, in the rise of the global financial crisis, G20 was for the first time held on a leaders’ level. Ever since, the G20’s central event is the meetings of leaders, but it holds meetings on the ministerial and expert levels as well (Kirton 1999).

Since its establishment, the forum has transformed from a ministerial level coordination and discussion forum for addressing issues of public finance to the international body where leaders of the biggest economies in the world gather to discuss and address the most crucial of global long-term economic and structural challenges (Kirton 2015).

History of the G20

The current G20 forum was announced by the financial ministers of the G7 with the idea to establish an informal mechanism for dialogue among systemically important countries (G20 2018). On 25 September 1999, in an attempt to broaden dialogue between countries, the finance ministers and central bank governors of the G7 countries invited their “counterparts from a number of systemically important countries from regions around the world” to a meeting in Berlin in December 1999 (G20 2018). The main aim of the new forum, as issued in a joint communique, was to promote dialogue “among systemically important countries within the framework of the Bretton Woods institutional system” (G20 2018).

In that way, the new Group of Twenty (G20) forum of finance ministers and central bank governors was kick-started at the 1999 meeting of the finance ministers of G7 (Postel-Vinay 2014, p. 5). It was created as a platform for informal dialogue aiming to enhance coordination on important economic and financial issues among the systemically significant economies (Kirton 2015, p.16).

Only later, in the midst of the global financial crisis of 2008, did the G20 debut summits of the heads of state. In Washington (2008) and Pittsburg (2009), this broader forum of cooperation was acknowledged to be of a now higher importance for global coordination than the G8 (returned to G7 after the exclusion of Russia in 2014) (G20 Research Group 2019b).

The G20 added a leader-level summit in November 2008 to cope with the then arising global financial crisis. Much like the G8 (currently G7), membership in the G20 was restricted in accordance with the forum's mission, with it becoming an influential club of the world's high ranking powers (Kirton 2015, p.16).

The vision of a new global governance system which could foster a wider scope of relevant political decision-makers inspired the creation of different cooperation forums throughout the years, some of them considered a direct precursor to G20, and others – like the Asia-Pacific Economic Cooperation (APEC) forum in 1989 – only partially related and more locally focused (Kirton 2015, p.16).

A direct precursor to the G20 is the G22 group, also known as the Willard Group, after a hotel in Washington, DC, where the meeting took place (G20 2018). After the G22 meeting, a more representative forum was created. The G33 framework of cooperation was formed to facilitate dialogue between 33 industrialized countries. The G33 is considered the immediate predecessor of G20 (2018).

The G20 in Modern International Relations

The G20 member countries are Argentina, Australia, Brazil, Canada, China, France,

Germany, India, Indonesia, Italy, Japan, Mexico, Russia, Saudi Arabia, South Africa, South Korea, Turkey, the United Kingdom, the United States, and the European Union (G20 Research Group 2019a).

G20 member countries cover 60.8% of the world's land area, generated 85.2% of global gross domestic product (GDP), and were home to 64.3% of the world's population in 2013 (Eurostat 2013). The intergovernmental forum is considered to be the largest high-level cooperation initiative in the international relations system.

Compared to the G8, the G20 is considered to be a more representative summit which provides a forum for coordination not only to industrialized nations but to emerging economies as well (Larionova and Kirton 2015). In the light of the rising complexity of international interdependence, as well as the economic convergence between emerging economies and established economic leaders, the G20 is naturally connected to the G7, with the G7 remaining a forum for cooperation of the developed nations, whose decisions and statements do have an impact on political dialogue on the G20 level as well (Larionova and Kirton 2015).

The G20 does not have a permanent secretariat, and the agenda for the annual summits is proposed and prepared by the member that is to organize the next annual summit. The G20 summits are hosted by a different member country each year. The funding of the summit is provided by the host country. Each year the next presidency is decided based on rotation and regional representation. To ensure continuity of the talks, a coordination between the previous, the present, and the forthcoming presidency is set up (Alexander et al. 2016).

The countries are represented by the country officials of the highest level in accordance with their governmental structures. Each year, heads of state gather to discuss topics of strategic cooperation. Another important part of the G20 summit is considered to be the meetings of the members' financial ministers (Kirton 1999).

The European Union is a full member of the G20, alongside three of its Member States, France, Germany, and Italy, and it is represented

at the G20 summits by the President of the European Commission and the President of the European Council (2021).

The Managing Director of the IMF and the President of the World Bank, as well as the chairpersons of the International Monetary and Financial Committee and Development Committee of the IMF and World Bank can participate in the G20 summit discussions (G20 Research Group 2019a) (Table 1).

The G20 in Numbers (World Population Review 2021; Worldometer, 2021; Statista 2021; EC 2021)
 19 countries + EU
 Representing 4,682,214,273 people (excluding the countries from the EU that are not part of the G20 as separate stakeholders) (World Population Review 2021)
 A total of 78,401,514 km², equivalent to more than ½ of the total world land cover. (Worldometer, 2021)
 73,19% of global GDP* (Statista 2021).
 Around 80% of global trade (EC 2021)
 *Data is for 2019.

Participation of Other Countries and International Organizations

At the invitation of each presidency, key international organizations participate in G20 meetings

to provide substantive inputs and enrich the discussion.

Countries that are not represented at the G20 could attend the meetings if they were invited by one or more members of the forum. This is typically the case of Spain, which despite being one of the 20 biggest economies, is not formally a member of the G20, only through its European Union representation. Spain has a permanent invitation to attend the G20 forums (EC 2021).

International organizations that provide insights into particular problems of discussions attend G20 Working Groups. The OECD has a particular role in G20 meetings, as it participates in all G20 Working Group meetings and provides data, analytical reports, and proposals on specific topics, either solely or jointly with other international organizations (OECD 2019).

Summary

The G20 is nowadays considered one of the most important regular international leader summits. The discussions held at the forum are of key interest to various stakeholders, including other governments, international organizations, international business, and citizens. The

G20, Table 1 List of all G20 meetings (August 2021)

First meeting	14–15 November 2008	United States; Washington DC
Second meeting	April 2009	United Kingdom; London
Third meeting	24–25 September 2009	United States; Pittsburgh
Fourth meeting	26–27 June 2010	Canada; Toronto
Fifth meeting	11–12 November 2010	South Korea; Seoul
Sixth meeting	3–4 November 2011	France; Cannes
Seventh meeting	18–19 June 2012	Mexico; Los Cabos, San Jose del Cabo
Eight meeting	5–6 September 2013	Russia; St. Petersburg
Ninth meeting	15–16 November 2014	Australia; Brisbane
Tenth meeting	15–16 November 2015	Turkey; Antalya, Serik
Eleventh meeting	4–5 September 2016	China; Hangzhou
Twelfth meeting	7–8 July 2017	Germany; Hamburg
Thirteenth meeting	30 November–1 December 2018	Argentina; Buenos Aires
Fourteenth meeting	28–29 June 2019	Japan; Osaka
Fifteenth meeting	21–22 November 2020	Online (Saudi Arabia)
Sixteenth meeting	30–31 October 2021	Italy

G8; Group of eight; Group of seven

Definition

The G7 (Group of Seven) is an informal association of seven of the world’s largest leading industrialized economies – the USA, Canada, United Kingdom of Great Britain, France, Germany, Italy, and Japan – with Russia being the eighth member. The European Union is sometimes called “the 9th member,” as it has a right to attend and participate in G8 summits, but cannot be a host (University of Toronto 2019b).

The G7 cooperation operates through annual meetings of the heads of state of the countries from the group. The aim of the meetings is for leaders to discuss and coordinate action on crucial global economic and political challenges. G8 annual meetings take place in member countries who take turns at hosting the summit. The G8 also holds a number of ministerial level meetings throughout the year. The presidency of the group rotates annually among member countries, with the rotation order being: France, the USA, the UK,

Russia (suspended), Germany, Japan, Italy, and Canada (University of Toronto 2019a).

Historically, the G8 cooperation began in 1975 with the leaders of six industrialized nations gathering in France (the group first came to be known by the name Group of Six) (Margaret Thatcher Foundation 2019). It was later on with the inclusion of Canada and Russia (the latter being part of the group between 1997 and 2014) that this format of cooperation became known as the G8. Because of the rising influence of emerging economies, in 2009, as one of the results from the global financial crisis, the G7 (then still G8) was formally recognized to be of lesser importance than the Group of Twenty (G20) (Schmucker and Gnath 2010).

History of the G7

The G8 discussion forum originates in the 1970s. Its predecessor, formally known as the Library Group, was a similar informal periodic meeting of financial government representatives (Margaret Thatcher Foundation 2019).

The first summit was organized by the French President Valéry Giscard d'Estaing, and it was held in Chateau de Rambouillet, France, in 1975 (Margaret Thatcher Foundation 2019). The original members of the G6 that gathered in 1975 were France, Germany, Italy, Japan, the UK, and the USA (University of Toronto 2019a). At the time issues of the 1970s oil crisis and the post-Breton-Woods international monetary disorder dictated the need for close coordination between industrialized countries (Barry 2002).

It was at this first summit that the members of G6 agreed to meet annually (Margaret Thatcher Foundation 2019). In 1976 the G6 became the G7 when Canada attained membership (University of Toronto 2019a). In 1994 Russian representatives began to hold separate meetings with leaders of the G7 after the group's summits – a communication format which came to be known as the Political 8 (P8), or G7 + 1. In 1997 Russia became a guest observer, and a full participant in the 1998 G7 summit, with which the G8 was formed (Lin et al. 2006). Russia was excluded from the G8

after the Crimea crisis in 2014 (University of Toronto 2019a), with the forum logically being renamed to G7.

The Role of G7 in the International System

The G7's main purpose is to provide a forum for coordination between leaders of industrialized countries on crucial political and economic issues such as conflict resolution, promotion of trade, and coordination of actions for global economy issues. The agenda is set according to the necessities of the international circumstances.

The association does not have the governance structure of a typical organization in the sense that it has neither headquarters, nor permanent staff. The annual summit is preceded by groundwork for the discussion that is to be held on the summit, and it is executed by diplomatic agents. The summit is followed by a number of ministerial level meetings (University of Toronto 2019a).

The meetings and decisions taken at the G8 have led to collective action on different topics such as disease countering campaigns and announcement of development programs. The decisions taken at the G7 and the highlights of the discussion opinions are convened to the United Nations system as well. The G7's role in the international system has been conceived as intertwined with other international organizations (Kirton 2006).

Following the Pittsburg Summit of G20 in 2009, it was announced that the G20 would become the new primary coordination summit format for tackling global political, social, and economic issues, gradually giving way to the more inclusive format of G20 which includes structurally important emerging economies such as China and Brazil (Larionova and Kirton 2015).

The G7 and the Other Gs

The G7 has been one of the most influential informal cooperation forums in international relations

since it has been a coordination place for the world's most developed countries and world economic leaders. However, recent decades witnessed the rise of new economic superpowers such as China, and the ever-increasing importance of regional economic and political leaders such as Brazil and the countries of ASEAN. For that reason, the G7 has been considered to become a less relevant forum for the system of international decision making and international coordination. In 2008, amid the rise of the global financial crisis, at the Washington summit the G8 formally declared the much wider G20 forum as the more important cooperation gathering (Larionova and Kirton 2015).

In light of the rising complexity of international interdependence, as well as the economic convergence between emerging economies and established economic leaders, the G20 is naturally connected to the G7, with the G7 remaining a forum for cooperation of the developed nations, whose decisions and statements do have an impact on political dialogue on the G20 level as well (Kirton 2010; Larionova and Kirton 2015).

However, the G7 still contributes significantly in decision making complementing the much more diverse G20, as smaller groups of like-minded members tend to cooperate faster and reach to a decision on an emerging issue faster than forums hosting more diverse interests (Morin et al. 2019).

G8 Summits and Global Governance

The G7 is not a classic intergovernmental organization, in the sense that it does not have a Charter, headquarters, or permanent administration. G7 summits are held usually on an annual basis, with the member countries taking turns to host the meetings. The EU as an observer has no right to host G7 summits. The G7 does not create legally binding documents as a result from the meetings, rather it communicates the decisions taken at the summit through communiques or other political documents. This informality has been considered to provide a flexibility in the forum's mandate that

might be more efficient in decision making of emerging issues than traditional international organizations (Morin et al. 2019).

G7 summits have been considered as key regular meetings for political agenda setting within the international community. Which member country will host the meetings is decided on a rotational basis. The 2020 G7 meeting was hosted by the USA, and the 2021 G7 summit was hosted by the UK, with the main focus being the countries' recovery from the global COVID-19 pandemic (SDG Knowledge Hub 2021).

The G7 is considered to provide governance through three ways of interaction: through nonbinding self-commitments of its members to coordinate their national policies; through coordination with and within international institutions; and through the inclusion of private actors. While political dialogue and publicly announced self-commitments have been gaining the most of attention in G8 activities, it is more and more evident that policy coordination within a larger international framework, and nongovernmental organizations (NGOs), business and civil society engagement is essential to all G7 activities (Gstöhl 2006).

Action of G7 on the Topic of Environment and Development

As an informal body of coordination between the world's most developed countries, the G7 has been looked at when development issues are raised. The countries from the G7 have repeatedly turned their attention to issues of developing countries. In response to the proposed New Partnership for Africa's Development (NEPAD) initiative by African countries, the G7 launched a number of initiatives and agreements (Black 2012). A so-called "Third Way" to Africa initiative was launched despite it has been considered a continuation of the already established power dynamics between developed and developing countries (Black 2012).

Another key international problem that is strongly dependent on the actions taken by the

most developed countries is climate change governance, and advances into environmental protection regulations. Climate change emerged as an issue for G7 governance at the Tokyo Summit held on June 28–29, 1979 (Kirton and Kokotsis 2015). The second German-hosted Bonn Summit on May 2–4, 1985, brought a rediscovery of direction-setting achievements, defining “climate change” for the first time as an issue of national priority, having G7 leaders declare that environmental protection to be as equally valuable as economic growth (Kirton and Kokotsis 2015, p. 51). In terms of approving international legal principles of environmental regulations, G7 leaders have adopted and reaffirm the “polluter pays” principle, which is a fundamental principle in international greenhouse gas emissions regulation (Kirton and Kokotsis 2015, p. 51).

There have been a number of perceptions on the G7’s role in environmental governance. Some have argued that it has been a key stakeholder to the doctrine of liberal environmentalism where economic and market values are dominant (Kirton and Kokotsis 2015, p. 4). The G7 is also analyzed as a proponent of the paradigm of “embedded ecologism,” and as a stakeholder in the context of institutionalized international interdependence on critical issues such as climate change and biodiversity dynamics (Kirton and Kokotsis 2015, p. 5).

Criticism of G8

The criticism most commonly addressed toward the G7 is that it is a representative of the rich developed nations only and is not able to address the issues in global governance (Barry 2002).

The forum has also been criticized of not being representative in relation to the interests of multiple key stakeholders in the international system (Barry 2002). Despite the exclusive nature of the G7 is to some extent limiting the power of its political decisions, it is still a forum that provides crucial information about the political opinions of key actors in the sphere of international politics.

Summary

The G7 (G8) group has been deemed as the pivot of the “rich countries” in international politics and coordination. In recent years, most notably since the rise of the global financial crisis of 2008, the G7 has its place as a main high-level forum for political coordination to the more representative G20.

Despite that, the G7 is still a significant forum for political dialogue between the most developed countries in the world, and its statements and decisions are still an important factor for political decision-making in various fields of international relations, ranging from economic and developmental issues to environmental protection ones.

[Genetically engineered organisms](#); [Genetically modified products](#); [Transgenic organisms](#)

Definition

The World Health Organization defines genetically modified organisms (GMOs) as “organisms (i.e. plants, animals or microorganisms) in which the genetic material (DNA) has been altered in a

way that does not occur naturally by mating and/or natural recombination” (WHO, 2014). The technique by which the genetic materials are altered is known as *recombinant DNA technology* or *genetic engineering*. Basically, *Genetic engineering* is a technique of genetic manipulation where the genetic materials from a living organism are harvested, modified, or recombined (i.e., manipulated with other genes) and replaced in the same or a different organism to obtain the desired traits. The final products of genetic engineering or gene manipulation are the GMOs synonymously known as transgenic organisms. *Genetic engineering* is successfully employed to (1) treat medical conditions such as genetic defect – gene therapy – (2) develop medicines and vaccines; (3) develop crops that are resistance to drought, cold, flood, or herbicides; (4) enhance growth of animals or plants; (5) shorten the maturity or ripening time of fruits, vegetables, and grains; and (6) enable an organism to produce something, which normally it would not do by itself (e.g., producing human insulin from a microorganism to treat diabetes), among others. As a result, a wide variety of GMOs such as GM crops and animals, GM microorganisms, GM foods, GM medicine, GM vaccines, GM biologics, GM cosmetics, GM pesticides, and GM industrial feed-stock is developed for various uses by consumers. Although the topic of GMOs is fascinating, a detail discussion about all GMOs and their various aspects is beyond the scope of this paper. Therefore, this paper discusses on the use of GMOs in medical and pharmaceutical research and food and agriculture followed by their safety, benefits, and risks. Finally, the paper discusses about the labeling requirements of GMOs based on the American and European approaches.

Medical and Pharmaceuticals Research

Genetic engineering has long been employed in medical and pharmaceuticals research to understand the causes and symptoms of diseases; develop new medicines, biological organs, and other medical essentials for treatment; and invent vaccines for the prevention of diseases, among

others. For example, in 1978, the first genetically engineered human insulin was developed by inserting the genetic sequence of human insulin into the gene of a bacterium (*Escherichia coli*). Similarly, GM animals, also known as transgenic animals, have been created as a substitute for human organ donors to produce specific tissues and organs to be transplanted into human – a process known as xenotransplantation. Another application of GMOs is the development of genetically engineered pharmaceuticals protein such as α -1-antitrypsin (AAT) to treat emphysema (a lung disease) and cystic fibrosis (an inherited disease of the secretory gland). AAT is produced in milk of GM sheep by incorporating human gene to it, which carries code for synthesis of AAT. Further, gene therapy – genetic modification of human – is gaining popularity to treat some cancers and rare metabolic diseases. For example, sickle cell anemia (a hereditary disease that destroys red blood cell) can be treated by incorporating a desired gene (β -globin) into the stem cell of the patient and putting it back to the patient, which eliminates the need for a matching donor.

In addition to treatment of diseases, GMOs are being used to prevent diseases as well. For example, edible vaccines in GM tomatoes and GM potatoes have been developed to prevent measles, cholera, foot and mouth disease, and hepatitis B, C, and E by producing an antigenic protein (pathogen) in fruits or edible parts of a plant (Abeyesundara et al., 2017). When these fruits or edible parts are eaten, the antigenic protein gets absorbed into the bloodstream and stimulates the immune system to develop immunity against the pathogen from which the antigen was derived. Such vaccines are painless, cost-effective, and easier to transport, store, and administer than the traditional injectable vaccines, thereby offering an array of benefits, particularly to the developing countries. Further research is underway relating to the effectiveness of GM edible vaccine.

Besides prevention and treatment of diseases, GMOs are enormously used in the areas of medical and pharmaceutical research. The use of transgenic animal models such as mice, rabbits, and rodents is considered as one of the best

methodologies to understand the functions and role of gene in the context of susceptibility, clinical presentation, progression, and response to therapeutic intervention of diseases. For instance, transgenic rodents are extensively used to study the physiological function of specific gene and its disease biology at the level of the whole organism. Transgenic rodents are also exclusively used by the pharmaceutical companies for disease modeling and drug development. Because of the similarity in physiology and functions of genes between humans and rodents, critical aspects of disease pathology and disease processes can be experimentally created in transgenic rodents to understand the underlying disease mechanisms and develop new therapeutic drugs. Indeed, transgenic animal models have proven vital to test the efficacy, safety, and toxicity during the early stages of drug development. Transgenic animal models are also used to replace the nonhuman primate (NHP) models to express specific human genes, which can replace the use of NHP for testing drug interaction with that gene in human and NHP. In fact, WHO has approved the use of a transgenic mouse model to test neurovirulence of an oral polio vaccine – developed by GlaxoSmithKline – that was previously tested in NHP (GlaxoSmithKline, 2014). Alike human, transgenic animals are equally in use to conduct research for animal kingdom. Thus, it appears that medical and pharmaceutical researches seem to be impossible without the use of GMOs.

Now the question arises: what is the role of genetic engineering and GMOs in food and agriculture? The following sections focus on the role of GMOs in food and agriculture, its safety, benefits and risks, and labeling requirements.

Food and Agriculture

The most controversial area in the kingdom of GMOs is the GM food. Foods, such as bread, sour dough, sour milk and cream, yogurt, cheese, sour vegetables, fermented meat, vinegar, wine, and beer, among others, require fermentation technique. This technique is simple and produces foods of improved nutritional quality and high biological value. Because of

the simplicity of the technique, it is particularly beneficial for developing countries where rate of malnutrition is high and requires supply of nutritionally improved and easy-to-prepare foods. The influence of microorganisms is thus of great importance to produce quality foods and improve nutritional status of people. On the other hand, GM foods are derived from organisms whose genetic material such as DNA has been altered through the insertion of genes from one organism into a second organism in order to suppress, encourage, or otherwise alter particular genetic traits in the second organism (ECR, 1999).

Genetically modified produces benefit to both consumers and farmers in terms of lower prices, greater benefits for sustainability, and nutritional value. Genetically modified foods are also beneficial in prevention and treatment of deficiency diseases. For example, to prevent blindness caused by the lack of vitamin A in many developing countries, scientists have developed *golden rice* that contains carotenoids, a precursor of vitamin A. Similarly, GM rice known as *iron rice* with increased iron content has been developed to “counteract iron deficiency by altering its genome through the insertion of a gene from the *Aspergillus niger* fungus” (Pandey et al., 2011). Other examples of foods that may contain GM ingredients are the following: bread, pastry, biscuits, and snacks; flour from soy; oil from soybeans, cotton and canola; cornmeal and corn; sweets, chocolate, and ice cream; lecithin and milk from soy; glucose or glucose syrup from maize; sugar from sugar beets; meat substitutes; and other ingredients and additives, among others. Although benefits of GM foods contribute to GM food marketing and its technology transfer (Rodríguez-Entrena et al., 2013), transmission of GMOs into the environment and the marketing of GM foods have resulted in a public debate in many parts of the world, particularly relating to the safety of GM food and lack of trust in the technology. As a result, national and international laws, guidelines, and institutional structures have been designed to govern the use of DNA in GMOs by using basically the two approaches. The first – product-based – approach is “grounded in the principle that the products of recombinant DNA technology

are not inherently riskier than those made by conventional production methods” (Spohn, 1996). Therefore, it is redundant to formulate policies to regulate them. The second – process-based – approach is “founded on the idea that genetic modification has inherent risks and therefore requires additional specific studies, case-by-case analyses, and adaptations of pre-existing regulatory structures” (Oda, 2003). The following sections of the paper describe safety of GMOs, analyze benefits and risks, and explain the labeling requirements based on the American and European approaches.

Generally Recognized as Safe (GRAS)

GRAS is a US measure of food safety. The USA has declared GM foods as generally recognized as safe (GRAS), making it the largest producer of GM foods (James, 2012). The reason for the high demand of GM foods is that the GM technology increases harvest productivity by controlling pest- and herbicide-based diseases, and this decreases cost of production (Reilly, 1989). The GRAS statement influences positively consumers’ responses to GM food acceptance. The Canadian government also continues to promote GM foods as safe and inexpensive and stresses that GM foods are similar to natural-grown foods. Thus American and Canadian consumers find GM foods to be low risks and an excellent alternative to natural foods.

However, European policymakers view the GM technology as new and respond differently from the USA and Canada. Members of EU recommend “a risk assessment and demand a moratorium on the environmental release of such organisms until binding Community safety directives have been drawn up” (Isaac and Hobbs, 2002). As a result, the EU has established a strict regulatory framework to trace GMOs and its derived products to undergo an authorization process that aims to guarantee safety for human, animal, and environmental health. Following the European regulatory framework, Brazil enacted their own laws and oversight mechanism and created agencies in 2005 to safeguard activities relating to GMOs.

Benefits and Risks

GM food consumption can be measured in term of its benefits and risks posed by it (Ayyagari et al., 2011). Studies indicate that GM crops can save agricultural input and losses from pests, thus improving agricultural productivity (Huang et al., 2008). For example, insect resistance is achieved by incorporating into the plant a gene that induces the resistance. Virus resistance is achieved by introducing virus genes that cause plant diseases, making the plant less vulnerable to the diseases hence increasing productivity. Herbicide tolerance is achieved through the introduction of a gene from a herbicide-resistant bacterium, thus significantly lowering the use of herbicides. Indeed, GM crops have been adopted by millions of farmers in developed and developing countries.

However, as the technology of gene modification is relatively new and complex, fears abound that GM food may carry serious risks both to human health and environment. Some of the human risks in terms of GM foods relate to effects of (1) toxic and allergenic transgenic proteins on foods, (2) transgenic proteins on plant metabolism, (3) herbicides and their metabolites on the resistant crop varieties and species, and (4) transfer of transgenic constructions, primarily into the genomes of bacteria symbiotic with humans and animals such as *Escherichia coli*, *Lactobacillus (acidophilus, bifidus, bulgaricus, caucasicus)*, *Streptococcus thermophilus*, *Bifidobacterium*, etc. Environmental risks highlighted by Kulikov (2005) are (1) erosion of the crop varieties as GM plants are derived from the limited set of parental varieties; (2) cross-pollination with the wild-grown plants, resulting in decline in biodiversity of plants and emergence of super weeds; (3) transfer of the constructions to rhizosphere microflora; (4) toxic transgenic proteins affecting nontarget insects and disrupting the trophic chains; and (5) rapid development of resistance to the phytophagous insects, bacteria, fungi, and other pests.

Labeling

The USA and EU perceive different risks and benefits associated with GM foods due to their

biotechnology-based laws and policies (Sheingate, 2006). In the USA, GM foods are not labeled even though more than two-thirds of products in stores are GM foods (Byrne, 2010). On the other hand, countries in the EU and Russia have the mandatory labeling requirements for GM foods (CFS 2013). Sand (2006) states that the legal obligations to reveal risk information exist at four distinct levels in terms of disclosure to (1) governments, by environmental impact statements for the planning or licensing of specified projects, environmentally hazardous activities, risk-prone industries, or dangerous goods; (2) citizens, under *right-to-know* schemes for specified workplace environments or for the benefit of communities adjoining industrial facilities; (3) investors as part of corporate financial accounting schemes; and (4) consumers through a variety of labeling schemes ranging from hazard warnings to product-related or process-related certifications of

contents or origin. In China, the Ministry of Agriculture ensures that consumers have the *right to know* about GM food by making GM labeling mandatory (Kou et al., 2015). Regardless of evidence of harm, consumers have a right to know about the contents of what they are eating. Consumers do worry about the effects of GM foods on their health and environment (Shewfelt, 2016). Indeed, misleading claims relating to sugar and nutrition need to be verified. A credible labeling can maximize consumer awareness about GM foods and minimize health-related risks (Vecchio and Annunziata, 2015).

However, it is also argued that labeling GM foods may not be useful to consumers as they do not only rely on the label-based information but also on the diversity of the supply of food products which in fact may curtail consumer's choices. Further, GM labels may mislead some or many

Photo 5/17

Two featherless chickens peck around in some grass May 22, 2002 at the Hebrew University in Rehovot. Israeli scientists at the Agriculture department of the university have genetically engineered bare-skinned chickens as part of a research project to develop succulent, low fat poultry that is environmentally friendly. The naked chicken, as the bird has been dubbed, would also save poultry farmers large amounts of money on ventilation to prevent their chickens from overheating.

REUTERS/Havakuk Levson

Genetically Modified Organisms (GMOs), Fig. 1 Genetically Modified Featherless Chickens (GM, 2020)

consumers by making them falsely believe that the government thinks that GM foods do pose risks to health or the environment because it is not easy to show the benefits (Legge and Durant, 2010). Precisely for this reason, GM food labeling in EU may indicate that the GM food is not good. GMO opponents tend to frame the issue by eliciting emotions and impairing scientific evidence, whereas GMO proponents stress scientific evidence and its benefits.

Future Directions

It is interesting to note that countries have varying degree of acceptance of GMOs depending upon the interplay of political and social orientations. Some countries (e.g., the USA, Argentina, and Canada) overwhelmingly support GMOs, whereas others (e.g., France, USSR) oppose it. Although food products are generally recognized as safe and low involvement products, consumers may get highly involved, and their anxiety heightened due to the unpredictable nature of GM foods (Hughner et al., 2007). Further, it is a daunting task for consumers to establish veracity of claims as they may not have the necessary scientific and technical knowledge of GM technology or the resources such as the laboratory, leading to consumer mistrust. In this regard, the consumers would greatly benefit from more balanced and consistent information on GM food labeling requirements.

Governments in many developing countries have shown reluctance to approve cultivation of GM crops. This may be due to inadequate safety information availability about the technology and poor understanding of potential benefits and risks of GM crops. Therefore, it is recommended that feasibility study be conducted relating to GM food acceptability and GM technology marketability before GM food commercialization. Almeida et al. (2015) find that some farmers are willing to cultivate GM seeds after receiving information on the potential benefits and risks of the technology. European farmers and industrial food producers

may miss the opportunity to profit from the benefits of GMO use. Because the regulation is at EU level, this is applied equally to all farmers and producers, leaving no one with competitive advantages for that reason. The next generation of GMOs and GM foods will be unimaginable – scientists are eager to grow featherless chicken (Fig. 1) to save time to undress them and hence higher productivity in addition to the enhanced nutrients (GM, 2020) of course, designer babies too – more beautiful!

'Designer babies' could be just two years away, expert claims

By Jack Guy, CNN

Updated at 6:24 AM on Tuesday, November 19

(CNN) • Genetically-modified babies are "highly desirable" to help protect people from disease and could be created ethically within two years, according to a new scientific paper.

Definition

Geoengineering, or climate engineering, designates technologies that can or could be, in a more or less distant future, deployed for altering Earth's climate. The goal is to counterbalance climate change or some of its effects (e.g., temperatures' surge). Their attractiveness stems from nations' difficulties for coordinating cuts in carbon dioxide (CO₂) and other greenhouse gas (GHG) emissions such as methane, nitrous oxide. Geoengineering technologies are commonly divided into two categories: *carbon dioxide removal* (CDR) and *solar radiation management* (SRM). CDR consists in extracting CO₂ from the atmosphere and storing it. Techniques vary from enhancing natural processes, e.g., by reforesting large areas and increasing photosynthesis, to more complex steps like installing capture devices on factories. SRM is about ramping out the albedo, i.e., Earth's capacity of reflecting solar radiation. SRM can or potentially could be achieved through various means: stratospheric aerosol injection of chemical components as sulfuric acid, spraying sea water droplets from boats for generating more white clouds (so-called cloud whitening), painting in white

streets (as in Los Angeles) and roofs, and so forth. The two sets of technologies (and the subsumed techniques) do not generate the exact same technical, political, and ethical issues, even if there is some overlap. If CDR remains in general uncontroversial on the principle (notwithstanding problems regarding the storage itself), SRM raises serious governance and distributive concerns.

Introduction

Humanity has constantly shaped its “natural” environment, modifying vegetal species, domesticating animals, and altering landscape features. This influence is particularly visible since the Neolithic, when an agricultural revolution took place coupled with the spread of animal husbandry among other transformations. However, the scale of man-driven changes has been dramatically deepening in modern history. By burning fossil fuels along the industrialization process, the concentration of GHG in the atmosphere has been soaring, which impacts the whole Earth. Changes have been so drastic and profound that some scientists consider that we are now in the *Anthropocene* (derived from “anthropo-” human and suffix -cene used for designating geological series/epochs during the Cenozoic period, from 66 million years until now), a geological epoch which main force is humanity (Crutzen and Stoermer 2000).

Geo-, or climate, engineering is often presented as an answer to such transformations, which explains why the topic is gathering momentum (e.g., Shepherd 2009). It started to be tested after World War II. For instance, during the Vietnam War cloud seeding attempts were made for causing intense rains and disrupting the supply of Vietnamese insurgents on the Ho Chi Minh trail. Other major military powers had research programs.

From a civilian perspective, geoengineering can be interpreted as humanity fully assuming its responsibility by either canceling out its adverse influence on the climate (and returning to a hypothetical, “unaltered,” situation) or by pushing changes in a different, less harmful, direction. However, it is strongly criticized for various reasons.

One objection is that it perpetuates the Promethean project of shaping Earth according to human needs and desires, which is morally reprehensible. Another is the uncertainty carried by large-scale intervention in the Earth system, especially considering the complexity and fragmentary knowledge of the climate. Such an intervention may potentially generate broader and more serious climatic risks. Therefore, prudence would be crucial. A distinct criticism is to underline the most likely disparate impact of geoengineering on different regions. Indeed, it would not affect evenly world areas. For instance, sulfur aerosols might diversely alter precipitations all over the globe, some places receiving more and others less than previously.

Therefore, geoengineering raises at least three issues: one of (moral) acceptability (is it a legitimate activity?), one of governance (when and how to implement it?), and one of redistributive justice (how to allocate *fairly* the benefits and burdens resulting from climate manipulation? How to compensate those who suffer from these interventions?)

An Intentional Alteration

In the past, human beings have altered the environment, mainly at a local or regional scale for the best as for the worst (e.g., Easter Island, extinction of Australian megafauna). The Anthropocene is the first (still debated) geological epoch where humans are the driving force and, since recently, are aware of their impact. Although humans have been modifying the climate, geoengineering is more serious. It does not only refer to humans transforming the climate, but to doing so on purpose. Therefore, even if, conceptually, geoengineering could be voluntary or involuntary (climate change itself is the most prominent example of the latter since humans have not attempted at altering the climate, it has happened as a by-product of economic activity), geoengineering defines *intentional climate* transformation by means developed to this end.

There are two main families of technologies, each being characterized by technical specificities (e.g., degree of maturation, costs, risks, and

uncertainties) and ethical dimensions (e.g., governance, redistributive effects).

Carbon Dioxide Removal (CDR)

CDR technologies have in common to attempt at capturing and sequestering carbon in different kinds of “reservoirs” (plants, ocean bottom, deep geological layer, and so forth). The ultimate goal is to address the cause of climate change by lowering the concentration of CO₂ in the atmosphere.

The term designates a large array of techniques. Reforestation, afforestation (planting in areas without previous significant tree cover), or the development of wetlands can be counted as geoengineering since, under specific circumstances, it contributes to trapping carbon. To some extent, these are techniques which are the most accessible, but with an impact that may not be immediately noticeable. Also, they are land-use intensive, meaning that they require large spaces for being implemented, which is problematic considering the current growth of the world population.

Other techniques such as ocean fertilization (e.g., sprinkling iron on oceans for stimulating phytoplankton and photosynthesis) or biochar (burning biomass in the absence of oxygen) adopt a more interventionist approach by interfering into natural processes. Along means that mimic or support natural processes, CDR refers to costly technologies, still under development. A possibility is to capture CO₂ right at the point of emission through filters, i.e., at the chimney of the factory or power plant. An alternative is to pump CO₂ directly out of the atmosphere.

In general, if most options are, at least theoretically, practical, many remain (extremely) difficult to implement since they demand further development and ambitious investments. Therefore, the feasibility of CDR on a significant scale stays speculative. Moreover, storage may create serious hazards. For instance, if kept at the bottom of oceans, carbon may endanger marine life, especially when drifting. Depending on the deposit location, there could also be the risk of deadly

leaks like what happened during the Lake Nyos disaster in Cameroon in 1986.

The necessary investments and large-scale feasibility explain why CDR is usually less discussed than SRM. However, some carbon capture technologies have started to be developed by private companies. Moreover, since some of the techniques consist in supporting natural processes, so appearing at first sight less disruptive, it explains why concerns seem to be more focused on SRM.

Solar Radiation Management (SRM)

SRM is a second family of geoengineering technologies. The purpose is to diminish the radiative forcing (i.e., the amount of solar power absorbed by Earth) through an intensification of Earth's albedo (i.e., reflectivity). This could be done by improving the reflective properties of buildings, roads, etc. for instance by white painting them. An alternative is to have boats pumping in the air seawater droplets, which will lighten marine clouds and enhance their reflectivity. A controversial technique is to use specially designed aircraft that will drop in the stratosphere (second layer of the atmosphere comprised between the troposphere and the mesosphere) sulfur that will dim the atmosphere, e.g., sulfuric acid, sulfur dioxide, hydrogen sulfide.

SRM covers various techniques, few being immediately implementable at low cost (e.g., roof painting), others requiring more investments (e.g., stratospheric injection) whereas some flirting with science fiction (e.g., space reflectors). In addition, SRM technologies differ according to their zone of intervention: ground or sea level (roads, roofs, marine cloud whitening), stratosphere (e.g., sulfur aerosols), or space for the most ambitious (e.g., reflectors).

Among these techniques, stratospheric injection stands apart. The principle is to mimic the effect of a major volcanic eruption (on the model of the Pinatubo in 1991 but on a larger scale) by injecting sulfate in the stratosphere (so the particles remain floating for 1–2 years). The result is enhanced albedo, i.e., more sunlight reflected.

This technology attracts most of the attention and critiques, primarily because it is actively promoted by researchers and companies (e.g., David Keith and his SCoPEX, Bill Gates) whereas being attainable at low costs but high uncertainty. Furthermore, a state with enough resources for developing specific aircrafts could start geoengineering on its own (Smith and Wagner 2018). Contrary to options such as space reflectors, it appears to be feasible under reasonable assumptions and in the short run.

In addition, aerosol injection will have widespread effects, creating winners and losers at the global scale, stressing questions of international governance. Critiques suspect that it will lead to increase the temperature of stratosphere, deplete the ozone layer, and diminish precipitation worldwide. More worryingly, it does not tackle the fundamental issue – the concentration of CO₂ and other GHG such as methane – and focalize instead on one symptom: the rise of heat. Finally, by desynchronizing the amount of CO₂ with global temperatures, it triggers a risk of “termination shock” if coming to a sudden end. Such a shock could lead to a brutal surge in heat along with extreme events or, even, to upset climate for a long period by crossing a tipping point.

Reasons for Geoengineering

The major reason for considering geoengineering is the inability of national governments to agree on and enforce drastic emission cuts. This incapacity is exemplified by the failure of negotiations led since the 1992 Earth Summit in Rio especially under the United Nations Framework Convention on Climate Change (UNFCCC). If no significant progress is made on mitigation, trying to actively counterbalance climate change appears to be the main alternative to the status quo, which is precisely what geoengineering promises.

The overall situation has the traits of a tragedy of the commons (Hardin 1968). The majority of governments has the same short-term interests: pursuing development by burning, presumably cheap and readily available, fossil fuels which

by-product is a massive release of CO₂ and other GHGs in the “common” (atmosphere). However, all nations would be better off if they could collectively agree on decarbonizing their economy by relying on renewable energies. Such a decision would slow down and, at some future point in time hopefully, lower GHG concentration and, thus, preserve the “common,” which is in the best interest of every country in the long run. This conflict between short-term and long-term interests explains why most countries have a strong incentive to free ride by refusing to reduce or cheating on their GHG release: leaving to other nations the burden of mitigation.

In that context, geoengineering is regularly presented (e.g., Keith 2013) as offering several advantages. First of all, it will permit to gain time for reaching a global agreement on drastic GHG cuts. In sum, geoengineering, especially under the cheaper and more quickly feasible forms, will allow to keep in check GHG concentration and temperatures while implementing mitigation and adaptation strategies.

In rarer instances, advocates present it as a “plan B” or a plan of last resort, i.e., a fallback solution if mitigation fails. The idea is to mobilize climate engineering in the case of all other options (mostly GHG cuts) falter. Critiques contend that mitigation is the first best solution everything considered and geoengineering creates so much uncertainty.

Climate engineering can nonetheless be seen as necessary, especially when considering the current course of GHG emissions. Since there is little chance to respect the Paris Agreement (2015) (due to lack of reforms and the opposition of countries such as the United States), past and present emissions have been setting the world on a path for global warming well over 2°C for 2100, and the adverse consequences will last for centuries, if not longer. For avoiding the worst of it, it is vital to initiate “negative emissions” as soon as possible, viz., more carbon is removed from than pumping into the atmosphere every year. Considering our current emissions and the existing concentration of GHG, natural processes (even enhanced) may be insufficient. Therefore, CDR would be a necessary evil. Since humanity has

been changing the climate through fossil-fuel combustion, geoengineering could be interpreted as a manner of assuming responsibility for the Anthropocene.

Many of its advocates do not consider it as a panacea. Rather, they see it as an option for buying time for pursuing mitigation and adaptation or as a last-resort alternative if everything else fails. Furthermore, they claim that since geoengineering under one form or another should be on the table, there is an obligation to undertake scientific research on the topic for taking informed political decisions, point that is contested.

Reasons Against Geoengineering

Geoengineering in itself, more particularly SRM (stratospheric aerosols), is at the core of heated debates (e.g., Hamilton 2013). Paradoxically, advocates and critiques agree that it generates risks, uncertainties, as well as winners and losers. The points of contention are the nature, extent, and seriousness of such risks, the amount of uncertainty (adverse effects that escape probabilistic assessment), and the pertinence of scientifically investigating the options.

The most radical opponents argue that the very fact of researching and discussing these technologies render them more acceptable by decision makers and the general public. It also lures citizens and governments to pursue “business-as-usual.”

A worse problem is that it breeds moral hazard. Since governments, corporations and citizens know that there might be some “solutions” to tame climate change and most of its adverse consequences, they may feel less pressured to cut their emissions. To some extent, geoengineering may curtail efforts to successfully tackle the present situation in exchange for some inefficient, unrealistic, or very dangerous alternatives.

This last objection applies as much as to deploying than researching geoengineering. Other criticisms revolve around the following issues.

Geoengineering is bad in itself because it interferes with nature, which is intrinsically wrong. However, it could be replied that the choice is

not between disturbing the nature and abstaining from doing it since humanity is already dramatically changing the climate. Moreover, one could claim that doing nothing equates disrupting natural cycles of carbon for instance.

A variant of this criticism is to underline that by engineering the climate, humans are playing God. They pursue the Promethean project of dominating and modeling nature, the very project that has guided industrialization. It would then constitute the last step of hubris (i.e., arrogance) in the face of nature.

Another set of objections focuses on the possible negative consequences. Geoengineering would be morally problematic not so much in itself, but because of probable outcomes. Such a claim relies on risk assessment and stresses the unfavorable balance between potential benefits and costs. The “termination shocks” evoked for stratospheric aerosol injection fall within this category.

A formulation of this claim is to underline the risks of messing up with complex (and not properly understood yet) natural mechanisms. Climate engineering would generate too much uncertainty with looming catastrophic harms that would be global. Some version of the precautionary principle (idea that actions should be suspended in presence of extraordinary risks or grave uncertainty) comes into play in this line of argumentation.

Another criticism, opposite to the previous, is to stress the inefficiency of geoengineering in adequately addressing climate change (and challenges of the Anthropocene such as species mass extinction) by being incapable of cutting CO₂ and other GHG within a reasonable timespan. Stated differently, it offers poor “fixes” to the most serious difficulty humanity has faced. Geoengineering would then represent a fatal distraction, leading to waste time on the adaptation and, more importantly, mitigation agendas.

A third type of problem is properly political and raises the double issue of (distributive) justice and governance. Geoengineering is most likely to produce divergent effects depending on geographical locations. Some regions will benefit from a more clement climate whereas others will be affected by harsher than usual meteorological conditions (e.g., droughts, floods, hurricanes). In addition, it may

decrease rainfalls at the planet scale, warm the stratosphere, and deplete the ozone layer.

First, because of the high probability of disparate impacts, it would be necessary to negotiate internationally any geoengineering strategy. However, on this aspect, global politics suffer from the same shortcoming that pushes for geoengineering at first place: the extreme difficulty, if not impossibility, to coordinate sovereign countries. This is worsened by the fact that all outcomes are arduous to properly foresee before the actual implementation.

Second, once measures are set in motion, some will win, others will lose. A basic principle of justice posits that, in a situation where harms cannot be averted, victims ought to be compensated. This obligation is reinforced when individuals suffer from no fault of their own, have not agreed (which is very likely), and are hurt by actions undertaken by other individuals for their own benefits. In short, many will endure what economics call negative externalities, i.e., costs imposed on them without their consent to the advantage of other parties. Pollution is a common example.

The justice dimension goes beyond the present generations. If geoengineering legitimately underlines the fair distribution of benefits and burdens for the current generations, such questions are amplified when future ones are considered. Since transformations brought by climate change and geoengineering will deeply affect the daily life of human beings during centuries (if not more), future generations have a stake in decisions made now. Thus, before tampering with the climate, it is morally required to take into account the interests of the humans to come. The challenge is then to determine how to integrate such interests.

Considering the current international relations, it is very unlikely that sovereign states agree on a compensatory scheme. Thus, it is highly probable that geoengineering will produce unjust outcomes without redress. A further issue is the threat of ill-intended use. In line with its military past, it is possible to have governments deciding to conduct, for instance, stratospheric aerosol injection as a weapon.

The risk of malevolent deployment and difficulties of cooperation highlights a fundamental

shortcoming: (almost) absent and defective international governance. Due to the fact that geoengineering has broad and disparate effects, many of which cannot be foreseen, it would require that countries coordinate their efforts for research, planning, implementation, and management of the outcomes. However, climate change has the characteristics of a tragedy of commons, which jeopardizes any global governance.

Summary

Geoengineering refers to technologies that aim at altering the climate. The objective is to counterbalance the impact of climate change. These technologies are usually classified into two categories: carbon dioxide removal (CDR) and solar radiation management (SRM). CDR consists in extracting CO₂ from the atmosphere and storing it deep in the oceans or within Earth. SRM consists in increasing the albedo, i.e., Earth's capacity of reflecting back solar radiation. Geoengineering is reaching a momentum due to countries' inability to coordinate for addressing steeply rising greenhouse gas emissions and concentration. Therefore, climate engineering is seen as an option for gaining time in order to implement serious mitigation and adaptation measures. However, such an option has to answer various criticisms which stress the human arrogance underlying the whole project, the risks and uncertainties and the adverse impacts on part of the population. In any case, geoengineering is facing the same problem as other domains of climate policies: the lack of coordination among countries which tend to free ride on the necessary emissions cuts.

Definition

Serra da Estrela corresponds to a mountain territory in the central inland of Portugal, with relevant resources of geological and geomorphological interest, associated with its formative history and glacial modeling. The diversity of elements and forms associated with glaciations, the biodiversity, and the identities of the local ways of life promote Estrela as a natural laboratory, a space for education and science. In its territorial dimension, it integrates nine municipalities with an area of

2216 km² and a population of 170,000 inhabitants. The classification of Estrela Geopark by UNESCO implied a revaluation and a new dimension for its development and sustainability, by promoting a holistic strategy, based on its geography, natural heritage, cultural references, and the self-esteem of its communities (Fernandes; Castro & Tracana, 2021). Geopark Estrela has the mission of contributing to the protection, valorization, and dynamization of the natural and cultural heritage, with special emphasis on geological heritage, to deepen and disseminate scientific knowledge, promoting tourism and sustainable development of the Serra da Estrela. On the whole, Geopark seeks the development of an integrated development strategy, allied to enhancing heritage, fostering geoconservation, education, and tourism, and supported the construction of development strategies for the well-being of communities.

Introduction

The geodiversity and biodiversity of the Serra da Estrela, structured by its geomorphology and the marked presence of glacial and periglacial traces, establish in this mountain a natural heritage that is associated with the ways of life and cultural identities and support the classification as a UNESCO World Geopark. These elements, due to their preservation and heritage value, consolidate the natural laboratory dimension of this territory and the educational, scientific, and touristic value of this mountain. The geoconservation of heritage is one of the most important activities of a geopark, in the context of sustainable development of the territory, promoting the implementation of projects for the preservation of natural spaces, environmental education, enhancement of tourism, and activities that increase the welfare of local communities.

Estrela UNESCO Global Geopark

Estrela Geopark integrates the globality of mountain territory of Serra da Estrela, which gives it a geographical identity and territorial symbolism,

framed in a space bounded to the southwest by Serra do Açor, to the south by Cova da Beira, extending until the contact with the surface of the Iberian plateau to the northeast of Portugal. The Serra da Estrela represents the highest mountain in mainland Portugal, with 1993 meters in the Alto da Torre, and has a protection status (protected area) its classification as Parque Natural da Serra da Estrela (PNSE) (Fig. 1). The territory of the Estrela Geopark encompasses an extended area to include the main geological formations and processes that contributed to its geodiversity and classification as UNESCO Global Geopark (Fig. 2).

Serra da Estrela is the highest mountain range in mainland Portugal, is part of the Iberian Central Cordillera, and is “bounded by fault scarps, granite massifs occupy the central area forming a summit plateau between ci. 1400 and 2000 m, while surrounding the core area, there is an interplay with schists and greywackes” (Vieira, 2004: 38). The territory translates a differentiated mosaic of landscapes, as a result of geological transformations, climatic contrasts, and forms of occupation over time, creating an ecocultural memory to be valued and preserved.

Geodiversity highlights are the following: “glacial landscape with geosites of international scientific relevance; a rich diversity of geosites of national relevance (e.g. tectonic, periglacial, granite landforms, hydrogeological, petrological and mining); numerous geosites with very high educative and touristic relevance; excellent access to most geosites; long history of geological and geomorphological research” (Gomes et al., 2018: 89).

The Estrela Geopark: Axes of Action

For geoconservation and environment, it is intended to establish a geoconservation strategy in which all natural values should be included, covering not only biodiversity but also geodiversity, promoting actions that consider in a holistic and integrated way all the ecocultural heritage and ensure careful and sustainable management procedures, capable of recognizing the vulnerability of this heritage and its valorization in collective strategies and with the effective participation of the communities.

Geopark Serra da Estrela, Fig. 1 Associação Estrela Geoparque – location and altimetry map

A strategy is implemented in the territory that aims to increase scientific knowledge, through a network of science and education, thus allowing to make the Estrela Geopark a competitive pole in research in mountain areas and the promotion of geosciences. Establish partnerships with several higher education institutions and research centers allow to develop studies and achieve capabilities for a better knowledge of natural history, in particular geomorphology, climatic conditions, and ongoing changes that affect the Serra da Estrela region and its heritage. Thus, and with a focus on various areas, such as geology, biology, or tourism, new, better-grounded strategies can be put in place that will contribute to the sustainable development of the territory.

Geopark Estrela has defined an innovative geoconservation strategy that allows the monitoring, valuation, and integration of the different 124 geosites, assessing their degree of

vulnerability resulting from both natural and anthropogenic processes (Fernandes et al., 2016; Gomes et al., 2017; Gomes et al., 2018).

Education is a pillar of geotourism and the sustainability of heritage for visitors and local communities. The means and supports for knowledge, didactic interpretation, and dissemination are crucial both for the enhancement and protection of these resources. Geotourism allows the promotion of geological heritage, science, and community valuation, promoting awareness for a concerted geoconservation. Geoparks emphasize a collective development strategy, promoting the conciliation of responsibilities (environmental, social, and economic) that are currently projected in a solidary and cooperative way in the municipalities of Serra da Estrela in actions of enhancement, conservation, and territorial promotion, through the creation of Estrela Geopark.

Thus, education or geoeducation, in the scope of the world Geoparks of UNESCO, is a key instrument for the awareness of communities and the recognition of the importance of preservation of the geological heritage (Brilha, 2004; Brilha, 2005; UNESCO, 2015). Tourism corresponds to a relevant process for the economy of the communities and important contribution to the valorization of the Geopark's resources, allowing: to expand tourist demand; to develop differentiated tourist products; to strengthen protocols and partnerships among the different players; to strengthen a tourist brand based on heritage and culture; to bring the community closer to the managing entities; and to promote support for the destination's qualification and territorial cohesion.

Communication assumes a prominent role in the knowledge, appreciation, and attraction of the Estrela Geopark, being determinate in an integrated and participative development

strategy (Fernandes et al., 2021) (Fig. 3). The communication promotes a bigger conscience of the Estrela Geopark brand, its value, and territorial and patrimonial meaning, foment the spreading and dissemination of the territory and its patrimonial, didactic, scientific, and cultural values, and generates a bigger attraction for tourists and investments, generating opportunities for the local population and the creation of jobs and services.

As tourism is a determining factor in the economy of the region, the focus should be on this given a more sustainable and diversified offer. For this, it is necessary to make a bet on other tourist aspects such as Nature Tourism, Scientific Tourism, and Wellness Tourism. A focus on a new development policy focused on the above elements will allow for the creation of new investment opportunities that can therefore contribute to mitigating the demographic trends currently observed.

Geopark Serra da Estrela, Fig. 3 Conceptual framework of the Estrela Geopark and effects on the valorization of the territory

As a UNESCO program is in the pipeline, the 2030 Agenda Sustainable Development Goals must be taken into account. The International Geoscience and Geopark Program (IGGP) is one of the instruments of the United Nations to implement this agenda, and some objectives, such as the Reduction of Inequalities (SDG 10), reducing inequalities within and between countries, the Climate Action (SDG 13), urgent measures to mitigate this global problem, and Sustainable Cities and Communities (SDG 11), contributing to the sustainability of the classified territories.

Final Remarks

The territory of the Estrela Geopark has an unmistakable geological heritage, with its focus on the

most important forms associated with glacialism, periglacialism, and fluvioglacialism in Portugal, some of them of international relevance. Its landscapes and mountain environment make this territory a “living laboratory” for studying the Earth dynamics, linked to climate change and natural hazards, mountain ecosystems, and tourism. However, in addition to the natural heritage the ancient history of human occupation enriches this classification, examples being the ancient practice of transhumance that is part of the culture of this territory, and which is the origin of the real name of this mountain – Estrela.

The classification of Estrela as a UNESCO Global Geopark results from a collective development strategy, anchored in the geological heritage and the valorization of the territory, articulating education, science, and tourism. It brings a

challenge and a responsibility for the governance, particularly to improve sustainability strategies, promoting networking among the different actors in the territory. This classification fosters identity, preservation, and self-esteem for the community.

Summary

Estrela Geopark comprises a geographically defined territory, with resources of geological and geomorphological interest of international relevance. The Estrela Geopark allows for enhancing, disseminating, and preserving resources that allow the promotion of educational, scientific, touristic, and social strategies in an articulated and transversal way. The diversity of resources (natural and cultural), the richness of its heritage, and the singular character of the landscape make Estrela a geography with an identity and ability to promote sustainable development, combining a strong tourist brand.

Definition

Geotourism can be described as trips to places of geological relevance where an experience of observation, interpretation, and learning is

developed with the several components of geodiversity of a territory, where the relationship between nature and the community is established in a symbiotic way, including scientific research, education, and cultural development. In this framework, geology induces processes and strategies of territorial valorization, promoting scientific research, geoconservation, and development with the promotion of tourist services associated with geotourism and the involvement of local communities. The relationship between the natural heritage elements of a territory, the associated scientific and didactic value, and the recognition of their value and interest (economic and social) for the communities implies increasing responsibility in their preservation and in the development of good practices of heritage management and promotion of social welfare. Geotourism, which involves direct contact with a territory and its geological elements, is an active site of interpretation and learning, associated with the displacements, paths, and routes constituting a dynamic tourist practice, involving knowledge in a relationship with nature and healthy physical activity. Geotourism, in terms of the importance that its territorial experience represents, implies the involvement of several players (public and private), including administrative entities, training and research institutions, local associations, and the communities themselves, in an articulation of knowledge, interests, and capacity that contribute to development and sustainability.

Introduction

The relationship between the territory, the scientific and didactic value of geological resources, the valorization of outdoor experiences, the preservation of heritage elements, and the interest of communities in their preservation foster processes of tourism valorization. Geodiversity and geological heritage are currently emerging as factors of sustainable development of rural and natural areas, associated with culture and lifestyles of the respective communities and fostering interest and attraction for tourists, particularly when

framed in classified and protected spaces, such as Natural Parks or UNESCO Global Geoparks.

Geotourism, Territorial Valorization, and Sustainability

Geotourism reveals itself as an opportunity for enhancement and sustainability of markedly natural territories, whose greatest resource is nature itself and the elements that structure its landscape, promoting territorial recognition, preservation, and tourism interest. In this context, and considering the effects that can be perceived, there are four basic aspects associated with geotourism: heritage (natural and cultural), preservation, interpretation, and sustainability. This approach translates a differentiating perspective of the tourist perception and appropriation of the territories, in which the landscape and its structuring elements are at the center of the concept itself and constitute the inducing factors for displacement, interpretation, learning, and recreation. In a broad sense, the landscape represents and materializes the natural, historical, and cultural processes through which territories are built and identified, promoting, at different scales of observation, a tourist experience with geology and territory. Etymologically, geotourism comes from the terms “geo” and “tourism.” The first refers to the Earth while the second refers to the experience of travel. Geotourism allows tourists to come into contact with the geological elements and geomorphological structures of a site or territory, stimulating the interpretation of the landscape, and promoting the acquisition of knowledge about natural history and the development of communities and their ways of life. In 2002, the National Geographic Society, in conjunction with the Travel Industry Association, defined geotourism as a “tourism modality, sustains, enhances and values the geographical character of a place and its environmental, cultural, aesthetic and patrimonial components, as well as the well-being of its residents” (Stueve et al. 2002). Newsome and Dowling (2010, p. 8) defined it “as a form of natural area tourism that specifically focuses on geology and landscape. It promotes tourism to

geosites and the conservation of geo-diversity and an understanding of earth sciences through appreciation and learning. This is achieved through independent visits to geological features, use of geo-trails and view points, guided tours, geoactivities and patronage of geosite visitor centres.” According to Arouca Declaration (2011), geotourism is defined as “tourism that sustains and enhances the identity of a territory, considering its geology, environment, culture, aesthetic values, heritage and the well-being of its residents.”

Promoting geotourism is to promote a territory, to unravel a story of millions of years of geological formation, a heritage for humanity that should be known, understood, and protected. It is the use of infrastructure and access to services needed to create wealth and to promote resources that support social and economic activities.

This is a holistic approach that, by valuing geology, includes culture, history, and the ways of life of communities, embodying in the landscape the origin and identity of places and territories, in a sustainable tourism position that allows the conservation and enhancement of geological, biological, and cultural heritage, with benefit and well-being for its communities.

In terms of structuring, geotourism aims to fully understand and appreciate the environment, and the fact that the abiotic elements (from geology to climate) must be previously known, considering that these are determinants and configurators of the biotic elements produced locally. Thus, the physical/natural components influence the cultural landscape and consequently set conditions for how communities have settled and evolved. This approach relates the dimension of the environment and its components to a greater connection for resident and tourist populations with the environment in which they live or visit (Newsome and Dowling 2018).

Thus, geotourism brings contributions and responsibilities for geoconservation and environmental education both for residents and for those who visit the spaces of relevant geological interest (Rodrigues and Neto de Carvalho 2010; Shekhar et al. 2019). It is considered as a sustainable, educational, and locally beneficial practice,

through the contributions generated and associated with the tourism services involved. The involvement of local communities stimulates the process of valuation and conservation of geological resources, expands locally the supply of goods and services, and improves the quality of the tourist experience (Frey 2003; Mignon 2018). In this context geotourism can be a tool to generate income for the conservation management of resources, in addition to social and cultural benefits associated with tourism and leisure activities. The income generated or achieved (namely by heritage and/or environmental recognition) can finance geoconservation projects, research, educational materials, infrastructure or support equipment, and the development of a territorial brand. Thus, there are undoubtedly complementarities between local communities and tourists, in terms of geo-interpretation and revenues from tourism activities, which have an impact on geoconservation and broadening community incomes (Ehsan et al. 2012). Based on natural heritage and landscapes, geotourism promotes its inventory and the extension of its knowledge (Hose 2005), in a process of qualification of the destination for adequate responses to the demand, and simultaneously to benefit the local development and an image of protection associated with the territory.

Geotourism corresponds to a form of tourism based on natural heritage, supported by geological elements, but including the diversity of biotic and abiotic elements that structure the landscape, sanctioning sustainable development (Fig. 1). Thus, the basis of a geotourism strategy must be the didactic value of geosites, their local importance, and their connection to the territory as a whole, in a participatory and inclusive logic, allied to processes conducive to local development (Dowling 2009; Henriques et al. 2011; Hose 1995). The valences of its promotion are fundamental for the development of a work of valorization and dissemination. But education is not just for students. Education is one of the foundations of geotourism. Upon receiving the information the geotourist is learning through the didactic interpretative instruments that are provided. The monumentality, rarity, and scenic

Geotourism and Sustainability, Fig. 1 Structuring elements of geotourism and territorial sustainability

expression of the geological elements and structures imply their greater notability, visitation interest, and conservation. Thus, the more appealing geological resources are, the greater the interest in interpretation and more effective the dissemination and interest of visitors in the interpretation of these sites. Consequently, it is easier to transmit geoconservation and sustainability values, while involving the populations through the perceived value.

Geodiversity, through the physical expression it brings to locations, allows the construction of their identity, appearing “as a representation (an ideal that reveals meaning) as a material existence (the reality of living conditions)” (Harner 2001, p. 12). It must be said that cultural and biological aspects, appear intertwined or associated with the geology of the place, promoting a composite approach, thus fostering the preservation of geodiversity. These interconnections as analysis and interpretation allow that tourists can enjoy, learn and disclose the destination. This integrated approach of the landscape and local ways of life with the geological elements potentiates the development of tourist and didactic itineraries and routes, contributing to the promotion of its conservation and even its recognition as a natural laboratory (Ehsan et al.

2012; Hose & Vasiljević 2012). It is considered that associated with a tourism strategy there must be a territorial strategy supported by the valuation of endogenous resources, which enhances the development of tourism products in these areas of relevant natural value. “The articulation between geodiversity, biodiversity, history and local culture not only increases the potential of geotourism, but also diversifies and complements the offer, leveraging development strategies and social welfare” (Fernandes et al. 2021, p. 124).

Geology and geotourism have their most expressive representation in the Global Geoparks of UNESCO. “A Geopark is an area with a significance geological heritage, with a coherent and strong management structure and where a sustainable economic development strategy is in place” (UNESCO 2006, p. 2).

Geoparks stimulate economic activity and sustainable development through geotourism. The growing interest in knowledge of the land and its natural characteristics, associated with a brand such as UNESCO, expands and diversifies the number of visitors, and encourages, simultaneously, the entrepreneurship associated with services, commerce, crafts, and industry, as well as the self-esteem of communities through territorial

recognition and the potential associated with local geoproducts. This process of territorial affirmation and involvement of the various players requires a firm commitment and the development of a partnership with long-term public and political support to ensure geoconservation and the satisfaction of the several economic, social, and cultural local actors.

Geotourists, in search of an experience strongly related to the geographic aspects of a territory, intend to develop in loco the understanding and perception of the natural heritage, especially the geological one, and its implications in the structuring of landscapes and ways of life. Concerns with the conservation of geodiversity imply the development of efforts, including monetary efforts (concept of use) to visit these sites, seeking their qualification and the well-being of the local communities. At the same time they promote respect, valorization, and perpetuation of local culture as identity and self-esteem factors of their populations.

In this context, the UNESCO Global Geoparks promote the development and sustainability of territories whose geography, geological heritage, and cultural identities are of international interest and relevance. Geotourism emerges as a crucial activity in governance, in which the potential benefits offered by its development enable, in addition to heritage protection (including geological heritage and geodiversity), a collective strategy that is articulated with science, education, and the progressive welfare of communities, promoting territorial sustainability.

Summary

Geotourism corresponds to a form of tourism based on the visitation of natural heritage, with emphasis on geological elements and geodiversity, promoting a structured interpretation of the landscape and its ecocultural identities, seeking the conservation and enhancement of their identities (natural and cultural), and the development and sustainability of these places and social living heritage.

German Code of Best Practices

► German Corporate Governance Code

German Corporate Governance Code

Luisa Bosetti
Department of Economics and Management,
University of Brescia, Brescia, Italy

Synonyms

Cromme-Kodex; German code of best practices; German self-discipline code of corporate governance; German self-regulation code of corporate governance

Definition

The German Corporate Governance Code (GCGC) was introduced in 2002 to provide best practices of direction, control, and communication. The GCGC focuses on board composition, powers, responsibilities, and functioning, with the purpose of guiding companies to address deficiencies in their corporate governance and enhance transparency.

The GCGC is a form of soft law: in opposition to so-called hard law (i.e., mandatory legislation imposing corporate governance mechanisms), the GCGC is a self-discipline tool, which contains recommendations and suggestions that companies can choose to implement on a voluntary basis. More exactly, the Code establishes stricter corporate governance standards addressed to German listed companies and other corporations with access to capital markets, although non-listed companies are also encouraged to follow the Code.

According to the German Corporation Act and the Code itself, companies must declare their compliance with the GCGC in a specific statement; otherwise, they must explain the reasons why their behavior deviated from it. This solution derives from the “comply-or-explain” principle, which guarantees flexibility to companies with different size and shareholding structure and increases their transparency on corporate governance. Overall, the comply-or-explain principle enables each business to implement the most effective corporate governance system, in line with its own peculiarities.

An effective implementation of the GCGC also requires ethical and responsible behavior to ensure the company’s development in the interest of all shareholders, workforce, and other stakeholders. To this aim, since 2019 the GCGC has also promoted sustainable value creation, recommending the fair balance of economic, social, and environmental factors.

Introduction

Since the last decade of the twentieth century, an intense debate on corporate governance issues has

fueled the diffusion of codes of best practices. Germany officially adopted its corporate governance code in February 2002, 10 years after the UK had introduced its first code of best practice, the Cadbury Code, thus beginning a process of corporate governance improvement (Aguilera and Cuervo-Cazurra 2004) that would have spread all over the world.

Like other countries, Germany developed its code of best practices in an effort to quell criticisms and mistrust against its corporate governance system. However, the reasons behind the rethinking of German corporate governance were different from those prevailing abroad. Indeed, governance reforms in other countries had been usually undertaken after facing corporate failures or scandals (Enron, WorldCom, Parmalat, etc.), originated or amplified by a lack of ethics and transparency in business relationships and weak mechanisms of internal and external control (Mueller 2014). Conversely, Germany needed to enhance its governance model in order to make it more attractive to foreign investors and more understandable for the international community (Cromme 2001; Cromme 2005).

In this regard, the introduction of the German Corporate Governance Code (GCGC) should be considered as part of a more extensive corporate governance reform that started in the country in the mid-1990s, as a consequence of globalization and increasing competition, privatization, and liberalization of capital markets (Cromme 2005). Such changes were affecting the peculiar insider and relationship-based system that had long prevailed in Germany: in other words, a system marked by employees' participation to corporate governance ("codetermination") and strong connections and interlocks between industry and banks (Salvioni and Bosetti 2006; Astori and Bosetti 2010).

Bank loans were usually the most important source of funding for German companies. Banks traditionally benefited from the national legislation, which ensured great protection to creditors and paid lower attention to stockholders (Cromme 2005) and, in particular, minority shareholders (Rott 2009).

This situation became unsustainable with the advancing globalization of financial markets, which could offer new financing opportunities to German companies, especially listed ones. This could also counterbalance the decrease in financing from banks and governments, whose investments had slowed as a consequence of privatization (Cromme 2005). Unfortunately, despite the opportunities emerging in capital markets, German companies were often met with suspicion from foreign investors, who complained about their lack of transparency in corporate governance. This was indeed a weakness of German companies, in which relevant information was frequently internalized, as typical of insider systems (Rott 2009). Therefore, information asymmetry between managers, large stockholders, and banks, on the one hand, and minority shareholders, on the other, seemed to endanger the possibility for German companies to attract foreign investors.

Furthermore, even the existing rules on corporate governance that would have reassured the international community were difficult to find and understand because they were dispersed in different laws. In the 1990s, for example, a wave of legal initiatives had led to the enactment of the Securities Trading Act (1994), the Restructuring Act (1995), the Takeover Code (1995), the Control and Transparency in Business Law (1996), and the Third Act on the Promotion of Financial Markets (1998) (Cromme 2005; Goergen et al. 2008).

At the beginning of the millennium, corporate governance rules for German companies, and especially for those more exposed to possible interest from international financial markets, called for a comprehensive reorganization. In addition, to gain foreign investors' trust, it was essential to explain how corporate governance was practiced in Germany, based on the peculiarities of the country's business system. In May 2000, a government commission chaired by Professor Theodor Baums started to work on corporate governance issues and to reform the German Stock Corporation Law. In 2001, the Baums Commission concluded that German listed companies

needed a code of best practices and recommended the nomination of a separate commission to draw up such a document. To this end, on September 6, 2001, the Minister of Justice appointed a special commission under the chairmanship of Professor Gerhard Cromme, who had already been a member of the Baums Commission. The Cromme Commission was composed of 13 members representing different parties: large and medium non-financial firms, banks and investment companies, the stock exchange, employees, auditors, and the academia (Rott 2009). Such composition did not include politicians, which strengthened the independence of the Commission from the Ministry of Justice (Cromme 2001).

The Cromme Commission continued the work started by the Baums Commission. Moreover, it considered the recent experiences of two private initiatives promoted by a Berlin-based group of experts and the Frankfurt Panel on Corporate Governance, which had drafted two very different corporate governance codes in June and July 2000 respectively (Lütz et al. 2011). Although the different conception and content of the said codes, which had probably been equivocated in the German context (Werder et al. 2005), both the initiatives contributed to expanding the national debate on corporate governance; in particular, they stressed the necessity to adopt a common corporate governance code that should have helped German companies compete in the international environment.

From 2002 to 2022, 16 editions of the GCGC were published under the chairmanship of four different experts (Gerhard Cromme, Klaus-Peter Müller, Manfred Gentz, and Rolf Nonnenmacher), covering the key aspects of German corporate governance and its evolution.

While presenting amendments year after year, the structure of the Code remained largely unchanged until the 14th edition, released in 2017. After that, the GCGC was rethought with reference to the types of provisions provided and their contents, as well as the fundamental approach that German companies were expected to adopt in the exercise of corporate governance.

For the first time, the GCGC that was published in December 2019 introduced a

sustainability-based approach, underlining the company's role in the community and its responsibility toward society. Accordingly, the Code recommended that the potential effects of social and environmental factors on the business success should be properly taken into account by the corporate governance boards in charge of strategic and operating decisions.

The strong link between corporate governance, a company's economic growth, and sustainability, which had been made explicit in 2019, was further explained in the next update of the GCGC. In fact, the edition dated April 28, 2022, and currently in force presents sustainability as a leading principle for both the supervisory board and the management board, that is, the bodies on which the two-tier German corporate governance system is founded and the main addressees of the Code.

GCGC Provisions

The GCGC is a self-regulation tool (Lütz et al. 2011), which aims at improving corporate governance by means of “principles” (previously known as “prescriptions”), “recommendations,” and “suggestions” (Stiglbauer and Velte 2012). As principles derive from the law, they are mandatory for German listed companies and all other addressees of the Code. Conversely, recommendations and suggestions, which are introduced by the verbs “shall” and “should” respectively, consist in the national and international best practices that the GCGC intends to spread. The Code puts much more emphasis on recommendations than on suggestions; indeed, the comply-or-explain principle (Werder et al. 2005; Talaulicar and Werder 2008; Wilcox 2011; Seidl et al. 2013; Luo and Salterio 2014; Salvioni et al. 2015) applies just to the former. More exactly, Section 161(1) of the Stock Corporation Act obliges companies to publish an annual compliance declaration clarifying the reasons why they have deviated from recommendations. On the contrary, no explanation is required in case of departure from suggestions, which intend to inspire advancements in corporate governance.

Legal Basis, Addressees, and Aims of the GCGC

The GCGC finds its legal basis in Section 161 (1) of the Stock Corporation Act, which requires that every year listed corporations and other corporations issuing securities other than shares on capital markets declare their compliance with the Code. Therefore, the GCGC is primarily addressed to the said companies, although it can also be voluntarily adopted by non-listed enterprises.

The GCGC was originally issued on February 26, 2002, with the dual purpose of providing capital market observers with “a catalogue for evaluating good corporate governance” and designing a framework for individual companies to fill in. To remain effective, the Code underwent constant review and adaptation to the national and international developments of the business context. Up to now, the GCGC has been amended 15 times, even if its nature and basic content have largely remained the same until 2019.

The most significant improvement involved the Code’s inspiration and took place in the editions dated December 16, 2019, and April 28, 2022, respectively, which officially recognized the importance of sustainability for the achievement of companies’ best interests.

However, the Code has primarily served for many years to address the major criticisms to the German corporate governance system raised by foreign investors. In this regard, the GCGC has dealt with and explained, *inter alia*, the following matters, which still constitute a major part of the Code.

- *Stronger focus on shareholders’ interests.* The GCGC emphasizes shareholders’ rights and makes their exercise easier, for example, through the promotion of proxies bound by instructions and the Internet broadcasting of general meetings. This strong orientation to shareholders’ protection counterbalances the traditional emphasis of the German law on creditors’ protection.
- *Two-tier model of corporate governance.* The GCGC contains provisions to favor a positive

cooperation between the *supervisory board*, appointed by the shareholders and the employees’ representatives, and the *management board*, appointed by the supervisory board and responsible for running the company and creating value for shareholders, employees, and all other stakeholders. The promotion of a closer cooperation between the two boards required by the German legislation is essential to reassure foreign investors, who are much more familiar with the Anglo-American one-tier model. Since the latter consists of a single board including both executive and non-executive directors, it is supposed to be the most efficient corporate governance model as concerns the information flows, as well as the most effective one in relation to internal controls. However, the German supervisory board exercises a monitoring and consulting function toward the management board, similar to the non-executive directors who advise and control the executives in the Anglo-American one-tier system. The GCGC stresses the interaction between the supervisory board and the management board in order to improve the quality of corporate governance, for example, through a better and wider discussion of business opportunities and risks, strategies, and performances.

- *Greater transparency on German corporate governance.* The GCGC intends to increase transparency on decision-making processes and remuneration systems, for the benefit of all capital market operators and supervisors. According to the GCGC, the corporate website is a useful tool to reduce information asymmetry between large and minority shareholders; moreover, the usage of the Internet favors the timely dissemination of information. All listed companies must disseminate interim reports on their financial results, prepared in accordance with internationally recognized accounting and reporting principles. Companies are also expected to disclose all the performance incentives for members of the management board and the supervisory board. Unlike other codes, the German one allows rewarding the supervisory board members with a performance-

related remuneration linked to the sustainable growth of the company. Since this rule allows the supervisory board members to be rewarded for their contribution to the company's long-term success, the provision is certainly in line with the search for dialogue and cooperation between the supervisory board and the management board promoted by the GCGC. In addition, the rule stimulates the supervisory board to give suggestions and formulate assessments taking account of the social and environmental impacts of the company's activity.

- *Independence of supervisory board members.* Independence in the exercise of control functions is largely appreciated by minority shareholders and the financial community; however, independence could be questioned in a traditional relationship-based system. For this reason, the GCGC provides several rules to strengthen the independence of the supervisory board. Among others, independence must be guaranteed with respect to controlling shareholders, members of the management board, and major competitors of the company. Moreover, the risk that a conflict of interest arising from internal relationships may undermine the independence of the supervisory board is managed by imposing strict limits on its composition (e.g., the supervisory board can include no more than two former members of the management board). Finally, any and all members whose independence is put at risk by a relationship with a customer, a supplier, a lender, or any other business partner are required to provide in-depth and honest information to the supervisory board.
- *Auditors' independence.* Over the years, the GCGC has contributed to ensuring reliable controls on financial disclosure by requiring transparency on any relationships (professional, financial, etc.) between the statutory auditors and the company which could jeopardize the independence of auditing. An example of this lies in the consulting services the auditors provided or may provide to the company in the future.

The two most recent editions of the GCGC, released in 2019 and 2022, have stressed the connection between the company's best interests and the ability to manage activities with a sustainable approach. This emerges from the new emphasis of the Code on social and environmental issues, the proper management and disclosure of which are necessary for the company to obtain stakeholders' trust and consequent legitimacy to operate. To this end, the Code recommends that sustainability is put at the heart of management and supervision.

Therefore, the management board shall:

- Systematically identify and assess threats and opportunities associated with social and environmental factors
- Consider ecological and social impacts of corporate processes
- Reflect social and environmental concerns in corporate strategies and goals
- Implement an internal control system and risk management processes focused on both financial and non-financial matters
- Collect and process sustainability-related data, which shall be used in internal analyses and must be published in well-structured CSR reports

Similarly, the monitoring and advisory tasks performed by the supervisory board must also encompass sustainability issues in order to ensure valuable support to the management board. Obviously, this presupposes the appointment of supervisory board members who shall possess the desired skills and expertise in the sustainability issues relevant to the company and its group. In this regard, the GCGC influences the profile of the candidates to the supervisory board who should be proposed to the shareholders' meeting and the employees.

Likewise, the Code recommends that the audit committee, which must be established within the supervisory board to perform controls on the company's accountants and internal control system, includes members with knowledge and experience in the fields of sustainability reporting and assurance.

Finally, the GCGC contains provisions to promote diversity and gender participation, in line with today's ever-increasing demand for equal opportunities for all those who have the necessary knowledge, skills, and expertise to guide a business. On this specific matter, the Code provides principles and recommendations about the appointment of women to both the boards and top-management levels, thus supplementing the mandatory laws adopted in the country in 2015 and 2021 to define the composition of the supervisory board and the management board respectively. As concerns this subject, it is interesting to note that the German legislation imposes a 30% gender quota in the composition of the supervisory board, while it only requires the presence of one woman in management boards consisting of more than three members, regardless of the total dimension of the body. For this reason, the Code recommends that the supervisory board takes diversity into account when management board members are selected; in addition, the Code makes the supervisory board responsible for the respect of the legally required gender participation on the management board, but it also permits the supervisory board to adopt a higher female quota in the management board. Moreover, the Code addresses the appointment of female managers to executive positions, which is a task reserved for the management board. According to the GCGC, the management board must stipulate targets for the percentage of women in the two management levels below the board itself, and it shall consider diversity when it makes appointments to executive positions.

Compliance Rates

Several studies show that the GCGC has been widely accepted since its first introduction (Cromme 2005). The official compliance rates are calculated every year by the Berlin Centre of Corporate Governance on behalf of the GCGC Commission, based on the responses to a questionnaire administered to the GCGC addressees. Such survey has limitations, such as non-response

bias from companies that do not properly apply the Code; however, the data has revealed a positive trend as concerns the acceptance of both recommendations and suggestions since the very first years after the GCGC introduction (Stiglbauer and Velte 2012). From 2004 to 2010, the average compliance rate with recommendations grew constantly from 80% to 85.8%; similarly, an increase from 58% to 63.5% was registered for suggestions, despite a decrease to 57.5% in 2008.

A further survey confirmed the large acceptance of the GCGC (Werder and Turkali 2015). In 2014, the average compliance rate with recommendations reached 83.6%, signaling a notable improvement from 79.8% of the previous year, probably due to the implementation of some new recommendations introduced in the 2013 edition. In the same period, the application of suggestions reached 65.1%, with a moderate increase from 63.9%.

Given the importance of recommendations and related disclosure requirements in case of deviation, it is not surprising that recommendations always present higher compliance rates than suggestions do. In addition, whereas no suggestion reached a 100% compliance rate in 2014, 11 recommendations were implemented by all the surveyed companies (Werder and Turkali 2015). Such recommendations, *inter alia*, strongly encouraged:

- A more detailed specification of the management board's information duties toward the supervisory board
- The annual publication of the company's corporate governance report and corporate governance statement
- The use of by-laws for regulating the management board's activities
- Measures to prevent conflicts of interest for the management board members
- The role of the supervisory board chairman

Significant differences also emerged from the comparison between companies listed in different stock market segments according to their size

(Werder and Turkali 2015). For instance, in 2014 the compliance rates in the DAX index (i.e., the blue-chip index including the 30 German largest companies listed on the Frankfurt Stock Exchange) were 96.2% for recommendations and 78.3% for suggestions, while they were the lowest of all (68.4% and 53.3% respectively) in the General Standard segment. Moreover, a significant number of recommendations found application in all DAX companies, whereas they were disregarded in other market segments. Another study (Rapp et al. 2017) discovered full compliance with the GCGC (100%) by 10 DAX companies and 9 MDAX companies.

Empirical evidence demonstrates that bigger companies are better inclined to implement the GCGC provisions. This can be explained by their higher exposure to the international financial markets, which makes them a potential target for institutional investors. Therefore, such companies commit themselves to implementing corporate governance best practices in order to reduce risks (Stiglbauer and Velte 2012), strengthen shareholder confidence and raise capital. On the other hand, the relevant efforts necessary to improve corporate governance structures and procedures in accordance with the Code could be an obstacle for smaller companies to full compliance.

Summary

Since its first edition, the GCGC has drawn attention to the following topics:

- Shareholders' and general meetings
- Cooperation between management board and supervisory board
- Management board: tasks, responsibilities, composition, remuneration, and conflicts of interest
- Supervisory board: tasks and responsibilities, chairman's duties, internal committees, composition, remuneration, conflicts of interest, and efficiency review
- Transparency
- Reporting and audit of the annual financial statements

Even if the table of contents remained the same from 2002 to 2017, amendments were constantly introduced to maintain the consistence of the Code with the emerging issues of corporate governance in the German context. In particular, an appendix was included in the four editions released between 2013 and 2017 to help companies provide information on the structure of the remunerations paid to management board members.

Evidently, compensation policies have great importance for the sustainable and durable growth of companies. In particular, variable components of the remuneration can be used to guide the management behavior toward long-term goals, which should be set considering the different expectations converging in the company. In this regard, the remuneration of management board members has been increasingly linked to the achievement of social and environmental targets, in addition to financial ones, in line with the growing demand for sustainable management practices.

It is therefore anything but a coincidence that remuneration policies have attracted widespread attention in the two most recent editions of the GCGC, the contents of which can be classified as follows:

- Management and supervision
- Appointments to the management board
- Composition of the supervisory board
- Supervisory board procedures
- Conflicts of interest
- Transparency and external reporting
- Remuneration of the management board and the supervisory board

From a structural viewpoint, the main novelty lies in the statement of principles, which summarizes the essence of the most important legal rules. Moreover, companies are supposed to describe how they have implemented the principles, in accordance with the "apply-and-explain" approach: this supplements the comply-or-explain rule, which already works for recommendations. Transparency and clarity are indeed crucial to the proper assessment of a company's corporate governance system (Ștefănescu 2014).

With regard to contents, the most significant innovation consists in the sustainability-oriented approach that the GCGC supports and encourages more widely than in the past. Sustainability has become a reference for all the main corporate processes, from strategy setting to internal monitoring and external communication of results. In the GCGC currently in force, sustainability is also contemplated in relation to compensation policies: stronger principles and recommendations specifically establish that the management board remuneration shall create right incentives and provide adequate payment for the performance rendered, still remaining socially acceptable. Moreover, the remuneration system shall include a variable part linked to the achievement of agreed strategic targets, in order to stimulate the company's sustainable development in the long term. Individual payments of management board members must also be disclosed in a clear and understandable way in an annual remuneration report.

To conclude, it can be observed that the stipulations contained in the many editions of the GCGC can be distinguished into internal and external mechanisms of corporate governance (Rott 2009), both inspired by a socially responsible and sustainable management approach in the long run.

Internal mechanisms include prescriptions, recommendations, and suggestions about shareholders' rights and the functioning of the annual general meeting, as well as the composition and activities of the two boards (i.e., management board and supervisory board). The only two provisions of the Code concerning codetermination are also classifiable as internal mechanisms, which provide for the respect of the Codetermination Act in the composition of the supervisory board and the possibility for employees' representatives to prepare supervisory board meetings separately from shareholders' representatives.

External mechanisms refer to the procedures and tools to enhance transparency on corporate facts; reduce information asymmetry between large stockholders, minority shareholders, and all other stakeholders; and

improve the quality and credibility of the company's communication.

The co-existence of rules on internal and external mechanisms of corporate governance proves that the Code's purpose is twofold. On the one hand, the GCGC safeguards the traditional aspects of German corporate governance, such as the two-tier model and codetermination. On the other hand, the Code intensifies shareholders' and stakeholders' protection in a way that should make German listed firms more appealing in the international financial context. In this regard, the application of the Code should result in a more resolute capital market orientation of German firms, and it should extend some peculiarities of outsider systems to Germany's insider one, thus accelerating the path of convergence induced by globalization.

Introduction

Nicholas Capaldi founded the Global Corporate Governance Institute (GCGI) in 2013. The

Institute came into being to overcome the myopia of limited perspectives, outworn doctrines, tired prior agendas, and vested interests that have besieged our world. The Institute intends to bring together global scholars and practitioners from different fields with business/academic/cultural/religious and political leaders to form a global alliance dedicated to rethinking and integrating value issues into management practice, education, and development. The GCGI is a company limited by guarantee and registered in England. The GCGI has started to do this and continues its drive to meeting its mission through international conferences, seminars, and workshops, which it has organized in different countries around the world. As at the time of this writing, the GCGI has sponsored and championed conferences in four of our continents in the following countries: the UK (2014), China (2015), Germany (2016), Australia (2017), Spain (2018), United Arab Emirates (2019); the (2020) meeting will be held in Portugal (2020). Plans include South Africa in 2021 and Mexico in 2022. The Institute has continued to seek alliances with several companies and higher education institutions to meet the global call for a sustainable world. The Institute has evolved into an umbrella organization. It encourages, contributes to the formation of, and participates in other organizations and educational programs. A few examples include those run by the International Training Centre of the International Labour Organization (ITC-ILCO) under the leadership of Professor Liangrong Zu and Cologne Business School. The GCGI is also involved in a wide variety of local sustainability organizations such as the one founded by Professor Mara Del Baldo in Urbino, Italy, and an International CSR Forum organized by London Metropolitan University, UK, in July 2018. Plans include multiple conferences per year, an annual seminar for graduate students, and an annual summer workshop for junior scholars.

Brief History

After the successful publication of the *Springer Encyclopedia of Corporate Social Responsibility*,

Professor Nicholas Capaldi, Legendre- Soulé Distinguished Chair in Business Ethics at Loyola University, New Orleans, USA, suggested to Samuel Idowu, the editor-in-chief of the *Encyclopedia*, that a conference be held in London to bring together as many of the contributors as possible. Contributors were drawn from about 52 countries spread across the globe; many of these contributors understandably became members of the GCGI and have continued to support its global activities in the drive to make our world sustainable.

The first conference was held at the Surrey University in 2014 and was not only successful as a conference but it also made us realize the potential of creating a continuous global network of scholars to foster the research, publication, and general educational possibilities – in short, the social responsibility of a scholarly network. All the participants were convinced that the organization had a role to play in the globalized world of the second millennium.

Professors Idowu of London Metropolitan University and Professor Rene Schmidpeter of the Cologne Business School had already established a connection with Springer Publishing. Joined by and under the leadership of Professor Capaldi, the Global Corporate Governance Institute was established, and it included plans for an annual conference, publication of conference proceedings, lifetime achievement awards, summer schools, and a new journal, *The Journal of Corporate Social Responsibility*. The GCGI hopes to establish a certification process for different grades of member of the Global Institute soon.

Mission/Objectives/Focus Areas

Vision and Values: How We Work

The GCGI works with scholars, practitioners, and business to build a sustainable future for all the occupants of planet Earth.

The principles of sustainable business practices that the GCGI encourages all global citizens both corporate and individual are encompassed in the following:

- Have in place responsible and ethical corporate leaders and employees.
- All corporate entities, regardless of whether they are profit seeking or not profit seeking, free themselves from all forms of discrimination and unethical practices.
- All entities to glaringly embed responsible behavior through their core activities.
- Respect all international agreements on human rights and labor issues.
- Manage responsibly their actions in the following core areas of social responsibility social, environmental, and economic.
- Work with other partners to promote actions that would sustain our world.

Structure of Governance

The GCGI is managed by its three Executive Directors – the Chief Executive Officer and President – Professor Nicholas Capaldi, Loyola University, New Orleans, USA; the Deputy Chief Executive Officer and First Vice President Dr. Samuel O Idowu, London Metropolitan University, London, UK; and Vice President and Director of Operations Professor Rene Schmidpeter, Cologne Business School, Cologne, Germany. These three senior executives are supported by a Board of Directors whose role is to assist the GCGI in ensuring that the Institute continues to be fit for its purpose and a rotating Academic Advisory Board. The Boards, including the editorial advisory Board of the *Journal of Corporate Social Responsibility*, meet annually at the annual conference site.

Activities/Major Accomplishments/Contributions

1. In the Community

Its members work collaboratively to address key social issues and the needs of their local communities in relation to education and research, employability, and social economic development.

2. In the Environment

It supports and encourages its members and the organizations the work in to reduce their carbon emissions in the attempt to reduce the adverse impact of their activities on climate change.

3. Internationally

The GCGI aims to inspire, support, and challenge global CSR scholars and students to increase their positive impact on the environment where they operate and through their activities in order to become a catalyst for change in society.

Definition

Global governance is linked to the current trend that develops large-scale rules, leaving aside the dominant political structures of the twentieth century. In this way, civil society and the individual have taken over, with the states and international organizations taking a back seat (Callies & Renner 2009). An example of this paradigm shift is found in the post-Cold War scenario in which there is concern for the environment, the resolution of conflicts through non-judicial means, or the growing presence of civil society reclaiming respect for human rights.

A definition of global governance refers to the set of rules governing society's relationships on a global scale. Global governance refers to a contract that regulates global relations based on issues of concern to people such as the environment, migratory movements, terrorism, and corruption, among others (Cooper 2019).

There are therefore as many types of global governance as there are issues to develop. Below are some of the subjects that are being developed globally:

Environmental Governance and Management of the Planet

Climate change, oceanic and atmospheric pollution, nuclear risk and that of genetic manipulation, reduction and extinction of resources and biodiversity, and above all, a development model that does not respect the planet are examples of diverse ways in which this accelerated and probably irrevocable impact manifests itself.

Of the various areas of global governance, environmental management is the one that most urgently requires a global response to the crisis in the form of collective actions carried out by the human community as a whole (Tubiana & Martimon 2005). These actions should help strengthen the progressive construction of the global community through common objectives (Najam et al. 2007).

These objectives include quality leadership, a sound environmental policy with effective cohesion and coordination, good management of the

institutions that make up the environmental governance system, and, finally, the dissemination of environmental concerns and actions in other areas of international policy and action (Foro por una nueva gobernanza mundial (FnGM) 2009).

Economic Governance

International financial institutions have been unable to resolve market failures, which led to the 2008 crisis, and remain opaque and undemocratic organizations (Peemans 1992).

The market economy alone is unable to meet the needs of the population. Liberal capitalism is becoming a machine that produces more wealth concentrated in only a few hands, and leads the world community into chaos over the absence of redistribution.

Political and Institutional Governance

The construction of responsible global governance to adapt the political organization of society to globalization implies the formation of democratic political legitimacy at all levels of the territory (local, state, regional, and global) (Barnett & Duvall 2004).

Governance of Peace, Security, and Conflict Resolution

The bellicose environment that results from actions such as the fall of the Berlin Wall in 1989 or the attack on the Twin Towers in 2001 have produced a competitive nationalism in international relations that has contributed to increasing military budgets and scientific innovation, which has contributed to greater global insecurity (Zürn 2018a). Wars and conflicts have their causes in economic inequalities, social conflicts, religious sectarianism, territorial disputes, and control of key resources such as water and land. In all cases, a profound crisis of global governance is exposed.

The proposals for the governance of peace, security, and conflict resolution should devote more resources to improving people's lives (health, housing, food, work, etc.) and to education, including education in the values of peace, social justice, unity, and diversity (Brand 2005).

Governance of Education

Education suffers from severe budgetary constraints, affecting the quality of teaching as a public service. There are 80 million children (of which 44 million are girls) who do not go to school, and the exclusion of marginalized groups is increasing (26 million disabled children and 30 million children affected by various conflicts).

While universal access to education is essential, it must also be accompanied by an improvement in learning outcomes, especially in literacy and basic skills essential to poverty reduction (Zürn 2018b).

However, the growth of new technologies, especially the Internet, has developed a genuine global community of production and exchange of goods that is changing the behavior of society exponentially.

Global Governance Framework

Global governance is not a static concept, rather it changes depending on the historical moment in which you want to define its content (Andreani 2001). For example, in the years of the Cold War, global governance aimed to regulate and limit the power of states to avoid imbalances and the breakdown of the status quo.

Today, global governance seeks to gain weight in the fate of the world through actions that are above the power of states. This seeks to reduce the differences between political organizations. These differences are present between the public and the private, the inequalities and the rights of each legal system.

In this sense, the establishment of effective global governance, different from a standardized global government, needs to establish common rules to ensure social cohesion on a global scale (Coleman 2012). However, this strengthening of civil society highlights the problem that states must accept the loss of some of their sovereignty in favor of global governance.

However, the existing differences (environment, security, corruption, etc.) make it necessary to abandon bilateralism in favor of collective

action. The result of this paradigm shift results in a new model of representation and management with a global scope based on the issue to be resolved and not on the subjects involved in solving the problem (Diez et al. 2011).

All this has resulted in the birth of a civic consciousness led by movements and organizations that respond with solutions on a global scale, following principles based on integration and solidarity.

Effects of Global Governance: From States to Regions

Given the loss of prominence of the state in the area of global governance, a new construction is being proposed in which national governments gain prominence through their internal transformation and the construction of new forms of coexistence that best reflect real relationships between societies (Beck 2019).

The manifestations of this new form of state would be characterized by:

- The suppression of the distinction between internal affairs and foreign affairs.
- Mutual interference in internal affairs.
- The refusal to use force as a means of conflict resolution and, therefore, the codification of self-applicable rules of conduct.
- The progressive decline in the importance of borders.
- Security based on transparency, and reciprocal openness.

This paradigm shift does not mean that the state continues to represent the interests of citizens through social cohesion, the provision of public services, the exercise of law and justice, redistribution, and solidarity.

Nonetheless, articulated and democratic global governance means giving prominence to citizens and civil society through proposals in which local communities become the foundations of building global governance, together with the Citizens' Assemblies (Deacon et al. 2003).

The Basic Principles of Global Governance

Global governance is characterized by following a series of principles tacitly accepted by global actors in response to the problems identified worldwide.

Legitimacy

This principle implies that persons exercising authority are considered trustworthy on the basis of the common good and that society is based on an ethical and respected foundation (Calame 2019).

There exists a vicious cycle between legitimacy of international institutions and global governance due to the existence of gaps at the global level in issues of morality, legal foundations, and democratic recognition, among others. For example, the United Nations is often seen as a sham, with its democratic legitimacy limited by the right of veto of some large countries in the Security Council (Calame & Gustavo 2008).

In this sense, a common legal basis must be used to establish the necessary legitimacy (Keohane 2011). The establishment of this foundation can be based on three pillars: the UN Charter, the Universal Declaration of Human Rights, and the Charter of Human Responsibilities.

Exercise of Citizenship

Global governance involves the involvement of all in a common destiny, which would allow a balance between rights, power, and responsibilities, and that no power is exercised without control (Miller 2007).

The exercise of citizenship, therefore, is a necessary condition for the creation of any new global governance model.

Efficacy

Public and private institutions must demonstrate their competence and their ability to respond to the needs of society. However, in the absence of a form of political organization of the world community that is responsible and legitimate, it is the market that dominates international relations.

This makes global governance irresponsible and inefficient from the point of view of social needs and therefore illegitimate from a political point of view (Scholte 2007).

Cooperation

Everyone can contribute to strengthening the common good, while global governance should serve to organize relations and cooperation between different types of actors, both public and private, and between administrations according to commonly established procedures (Ocampo 2015).

This form of collaboration is the result of increased interdependence in organizations and civil society actors with each other, including the creation of forms of associations between public institutions.

Equality

Finding solutions to the problem of inequality is one of the goals of global governance. As a result, strong systems of solidarity and redistribution will need to be established to ensure the reduction of inequalities on the planet.

Global Governance Issues

Globalization implies the internationalization of the rules that regulate life on the planet. However, these transformations have been shown to be insufficient to meet the needs of world public policy. For example, moral deficiencies, democratic recognition, and the lack of charismatic leaders have created a deficit in the legitimacy of existing regimes (Keping 2018). All this can be improved by creating spaces for dialogue through the creation of the organization of global governance and the sharing of its objectives.

As for the formulation of objectives, the 17 SDGs show us how a program that pursues the preservation of humanity and the planet has enormous difficulties when regarding its application. One of the causes that could be argued to justify its failure is that citizen participation was non-existent throughout the elaboration process.

Global Organizations and Global Governance

While states remain powerful actors in global society, trust has diminished in their ability to adequately address the emerging challenges of a complex and interdependent world. This leads to demands for new approaches to international governance (Dingwerth & Pattberg 2006). In the absence of a global state that can serve as a basis for a democratic order, it is important to strengthen the role of international institutions to achieve an international governance space.

In this sense, the growth in the number of international institutions reflects the desire to replace the logic of states that pursue national interests, with the deliberative legitimacy present in international relations that are generated in these types of organizations.

However, it must be borne in mind that global governance is questioned about the democratic legitimacy and accountability of international institutions (Buchanan & Keohane 2006). Legitimate limits need to be established in order to develop the global exercise of power through their ability to structure processes of reasoning and deliberation in global society. To avoid this insecurity, control mechanisms have been created that seek global monitoring, such as:

- The establishment of international standards that set rules to control global policy.
- The creation of classifications and mappings based on neutral concepts.
- The construction of a common language that allows knowledge and experience sharing.

Intergovernmental institutions have been joined in recent decades by a wide variety of non-state actors, from transnational corporations, NGOs, and indigenous peoples, among others. Social media have facilitated the dispersion of information by giving voice to social movements, global audiences, and media organizations (Jaeger 2007).

The result seeks to convert all these non-state entities into sources of independent authority with a global voice.

Global Performance

Francesca Gennari
Department of Economics and Management,
University of Brescia, Brescia, Italy

Synonyms

Corporate global responsibility; Economic, social, and environmental performance; Shared value; Sustainability

Definition

Corporate performance is not an easy concept to define because it developed during the time according with external conditions and corporate approaches. Starting from Friedman (1962) who emphasized the dominance of the economic performance for shareholders to the stakeholder theory by Freeman (1984) that emphasized the corporate responsibility for all stakeholders, the ability by company to act according with different types of responsibility (legal, ethical, economic, social, environmental) was stressed.

The traditional concept of performance becomes a concept of global performance that embraces different performance measures, engages stakeholders in the creation of value, and leads to a reconsideration of the traditional relations with other actors of company's value chain and competitors.

Therefore, global performance means corporate actions are not limited to business boundaries but should produce value shared with society, taking place in the social progress according with a sustainable corporate approach.

Introduction

The concept of corporate performance is usually implied, but a precise definition proves to be elusive because of the variety of facets this concept is associated with.

Since the publication of the *Wealth of Nations* by Adam Smith (1776), for more than 200 years, the view of a firm which obtains its resources from investors, employees, and suppliers to produce goods and services for its customers dominated. According with this view, corporate performance is the financial return to the firm's owner from the consumption of tangible resources (Donaldson and Preston 1995).

The increasingly dynamic business environment, together with the change in the traditional factors of production, with an emphasis on immaterial resources, highlights that the concept of corporate performance cannot be reduced only to profitability or economic results. The spread of the concepts of corporate social responsibility (CSR) and sustainability extends the definition of corporate performance: company success is no longer based only on criteria of economic performance, but it is linked to the optimization of environmental and social performance too, according with the logic of corporate global responsibility and the creation of value in the long term.

This approach is based on the ability by company to balance the interests of all those who contribute with resources and consensus to the current and future company's success, generating satisfying results for all of them. It follows that the economic results are strongly influenced by the ability to maintain positive relationships with all relevant stakeholders (Freeman 1984; Carroll and Buchholtz 2006), leading to a profound change in the valuation of company's performance. The meaning of this last one becomes global considering the interrelations among competitive, economic, and socio-environmental variables and the concept of shared-value (that is the ability by company to create value for itself and accordingly for community) becomes crucial (Porter and Kramer 2011).

Theoretical Framework

The shareholder view (Friedman 1962) emphasized for long time the dominance of company's economic performance to satisfy financial expectations of shareholders. This often means the excessive stress for short-term profits in particular by boards of corporate governance systems characterized by wide dispersed ownership (the so-called outsider system of corporate governance), with the aim to obtain positive judgments by the financial markets and to reconfirm their role. This attention for short-term performance implies the risk of unethical conducts by boards oriented to personal or relevant shareholders' interests to the detriment of other stakeholders' categories. At the same way, unethical and fraudulent actions in corporate governance systems with concentrated and stable ownership (the so-called insider systems of corporate governance) were often caused by the will of majority shareholders, usually members of the board, to put economic performance over time under stress, increasing the company's value as a personal asset (Salvioni and Gennari 2016).

The diffusion of CSR principles and the valorization of stakeholder perspective (Freeman 1984; Freeman and Dmytriiev 2017) emphasize the concept of global corporate responsibility, going beyond the profit as the unique measure of corporate performance.

The different theories in the context of CSR highlight different aspects of performance.

According with social contract theory, the company's performance is evaluated as the adherence of corporate behaviors to what society implicitly expects business to operate, that is, the concept of compliance (Gray et al. 1996). According with legitimacy theory (Suchman 1995), performance expresses the use of power by business in a manner that society consider responsible and desirable, giving the company legitimacy to operate. Stakeholder theory (Freeman 1984) emphasizes the relationships between the company and its stakeholders as a source of competitive advantage. This approach promotes the equilibrium among economic, social, and

environmental performance in the long term, affirming a governance attitude aimed at balancing the natural trade-offs among the interests of different stakeholders that could be apparently at odds with one another (Goedhart et al. 2015).

Scholars suggested various models to depict and measure this new concept of global performance.

Carroll established four categories or domains of CSR, building a pyramid where economic responsibility is placed as the base because it is a foundational requirement in business. Being at the base of the pyramid, it must be strong to support the entire edifice, that is, society's other expectations toward enterprises (Carroll 1991). The order of the categories of responsibilities (economic, legal, ethical, and discretionary at the top) portrays the fundamental nature of these categories to the business existence in society: economic and legal responsibilities are required, and ethical and discretionary responsibilities are expected and desired. In particular, economic responsibility is about the production of goods and services that society wants; legal responsibility regards the respect of rules under which business is expected to operate; ethical responsibility is about the additional behaviors and activities which are not codified into law but are expected to business by society; and discretionary responsibilities are left to individual choice. The pyramid of CSR is intended to be seen from a stakeholder perspective wherein the focus is on the whole, instead of the different parts (Carroll 2016).

Based on this framework, the social corporate performance considers three aspects: one pertains to all that is included in the definition of social responsibility (the four categories of responsibilities); the second concerns the range of social issues management must address (e.g., environment, discrimination, product safety, etc.); the third is the philosophy of social responsiveness (reaction, defense, accommodation, proaction). This conceptual model remarks that social responsibility is not separate and distinct from economic performance, but it is part of the global responsibility of business. Therefore, economic

performance doesn't disappear in discussions about CSR; actually, it must be considered in a wide perspective of business that includes also the society's expectations.

Elkington (1994) depicted the CSR as a framework composed of social, environmental (or ecological), and financial dimensions. The triple bottom line (TBL) accounting expands the traditional reporting framework to take into account social and environmental performance in addition to financial one. The traditional measure of corporate profit is the bottom line of the profit and loss account, the second is the bottom line of the company's people account (a measure of how socially responsible an organization has been throughout its operations), and the third is the bottom line of the company's planet account (a measure of how environmentally responsible it has been). This model remarks the fact corporate performance should be accountable according with a global view where different dimensions nurture each other.

Porter and Kramer (2006, 2011) measure the performance as the ability by company to produce shared value, generating economic value in a way that also produces value for society, by addressing its challenges, connecting company success with social progress. Companies can pursue shared value opportunities on three levels: reconceiving products and markets (that means focusing on revenue growth, market share, and profitability which arise from the environmental, social, or economic development benefits delivered by a company's products and services); redefining productivity in the value chain (that is, the improvement in internal operations); and enabling cluster development (that derives from improving the external environment for the company through community investments and strengthening local suppliers, local institutions, and local infrastructures in ways which also enhance business productivity). For each shared value opportunity, companies identify and track both social and business results; their parallel goals are to address a social problem and improve business performance.

Therefore, over time the concept of performance became broader, including all the

dimensions of corporate success which together guarantee the company's survival in the long run, thanks to the ability to establish and manage relations with key stakeholders. In other words, the corporate global performance is the capability by company to satisfy stakeholders' expectations: when it happens, stakeholders keep giving resources and consensus to company, nourishing a virtuous business cycle that increases further consensus and resources.

Key Issues

In the last decades, because of the spread of CSR theories, the concept of corporate performance became global, including different dimensions of business results. The global success of the company in the long run is based on a balanced contribution by economic, social, and environmental conditions of success. In general, corporate performance is the capability by company to produce outputs and outcomes coherent with the stakeholders' expectations in the long run according with a sustainable approach to do business. This approach modifies the company's attitude toward economic results promoting the maximization of economic performance, according with a long-term vision that creates more value for everyone (shareholders included). In fact, the valorizations of CSR and the importance of the stakeholder view affirm a governance approach aimed at promoting the creation of corporate value over time, suggesting going beyond the excessive short-termism that characterizes short-sighted boards, this last often related to the relationship between the firm's owners and the management.

In this context, the management of stakeholder relationships becomes a source of competitive advantage (Hillman and Keim 2001; Brondoni 2003; Salvioni et al. 2016; Salvioni and Gennari 2017), depending both on the company's enhancement of connections among economic, competitive, and socio-environmental variables to be included in the strategies and the company's systems of accountability to communicate the performance results to stakeholders (Bosetti 2015).

The change in the approach toward CSR changes also the governance variables and their key performance indicators (KPIs): the awareness of a global concept of performance drives a global strategy idea, requiring the redesign of the internal control system and the connected tools for measuring and managing performance. Understanding the link between stakeholders' expectations and the company's needs, achievable thanks to stakeholders' contributions, is a critical aspect in the development of corporate goals and strategies. In addition to traditional financial performance indicators, new indicators about social and environmental dimensions should be added too, and new tools for the performance measurement should be developed. Measurement makes CSR strategies tangible for internal and external stakeholders too.

The communication needs are often the drivers for the insertion of socio-environmental indicators in the management processes. The virtuous cycle where the stakeholders' resources make possible the business activities which generate results appreciated by stakeholders is based on an effective communication by company. The extension of the concept of corporate performance implies also the extension of the conveyed information: the communication is intended to be global, that is, referred to the global responsibility company has toward its stakeholders.

This new way of reporting and communication has both internal and external benefits. Internal benefits for company can include a better understanding of risks and opportunities, the emphasis on the link between financial and nonfinancial performance, the benchmarking, and the assessing of global performance with respect to laws, norms, voluntary initiatives, and other companies. External benefits are mainly connected with enabling stakeholders to understand the company's true value and its capability to create shared value, demonstrating how company influences and is influenced by expectations about sustainable development in the long run, improving reputation and relations with stakeholders.

Companies can communicate their performance about different dimensions of responsibilities by means of separate reporting: financial

statements for economic dimensions, and social and/or environmental reporting for socio-environmental dimensions. Instead of separate reports, the integrated reporting is a way to give a joint view on global performance. It aims at communicating how a company creates value in the short, medium and long term, considering various forms of tangible (as financial) and intangible (as intellectual, human, social and relationship, natural, etc.) capital. The integrated reporting gives a united view on the interrelation among the different measures of performance, emphasizing the systemic idea of business. The ability of an organization to create value for itself enables financial returns to the providers of financial capital. This is interrelated with the value the organization creates for other stakeholders, society, and environment through a wide range of activities, interactions, and relationships. When these are significant for the organization's ability to create value for itself, they are included in the integrated reporting (IIRC 2013).

The importance of a global communication has led also the European Commission to intervene with a Directive (2014/95/EU) regarding disclosure of nonfinancial information by certain large undertakings and groups.

Summary

The competitive context is making CSR even more complicated, considering the global impact of this issue and the global engagement requested to nations, companies, organizations, and citizens (see ► [“United Nations Agenda 2030 on Sustainable Development Goals, The”](#)). Companies need to be aware of this, and they need tools to reduce their exposure to “responsibility failures,” managing the relations with stakeholders and creating shared value according with a sustainable strategic approach.

Having a global view on different stakeholders' expectations is the first step to organize business activities in order to satisfy these expectations, creating value for stakeholders and company itself. The traditional concept of performance becomes a concept of global performance

that embraces financial, social, and environmental performance measures, engages stakeholders in the creation of value by company, and leads to a reconsideration of the traditional relations with other actors of company's value chain and competitors.

The multidimensionality of performance requires new CSR performance measurement frameworks (as CSR Balanced Scorecard, GRI Guidelines, AA1000s, etc.). CSR-related tools can support a developmental approach to CSR, encouraging innovation and continuous improvement on the basis of partnerships and joint communicating and engaging with stakeholders (European Commission 2003).

Engaging with stakeholders, which are the individuals, groups of individuals, and/or organizations that are affected by or can affect an organization's activities, and responding to their concerns improve corporate performance (AccountAbility 2015). A quality stakeholder engagement can lead to more equitable and sustainable social development by giving those who have a right to be heard the opportunity to be considered in decision-making processes; help to determine the most important issues for sustainability management and reporting; enable better management of risk and reputation; allow for the pooling of resources (knowledge, people, money, and technology) to solve problems and reach goals that cannot be reached by single organizations; enable understanding of complex operating environments; enable learning from stakeholders; inform, educate, and influence stakeholders in ways that can improve their decisions and actions, which in turn will have an impact on the organization and society; and contribute to the development of trust-based and transparent stakeholder relationships (AccountAbility 2015, pp. 5–6).

The corporate performance expresses the ability to manage the key drivers for success within the entire value chain: the global performance refers also to the global value produced by all the actors involved into business. Network-based business models are developing, because of the awareness that rigid resource-based systems are

becoming obsolete. Value is seen as a stakeholder-based concept where the performance expectations of all participants must be met for the continuous success of the value chain network. This is achieved by integrating and coordinating the assets, processes, and capabilities of stakeholders to create an optimal value output, such that each stakeholder's resources receive satisfactory returns. In this context, the cooperative arrangements or networking is the necessary response to global and less predictable markets.

A new exclusive vocabulary accompanied this “new economy” approach (Walters 2009): collaboration (that describes the overall willingness of organization to seek and implement customer-based solutions using shared resources and producing shared benefits), co-destiny (used to ascertain the extent to which members of a business coalition share the same objectives, strategies, and values), co-opetition (that describes the situation in which competitors work together to meet individual goals using mutual facilities) are increasingly widespread words.

Hence, the change in the corporate vision embracing CSR approach involves all of the aspects of the business: corporate goals, strategies, performance indicators, reporting, and relations with stakeholders. The success of CSR in business depends on the motivation and the engagement of all actors involved for the development of a real culture of sustainable development. Corporate boards can have a pivotal role, appearing as “change agents” (Maritz et al. 2011), in favoring the adoption of a concept of global corporate performance.

University of Yasar, Izmir, Turkey

Synonyms

GRI; GRI reporting; Sustainability reporting

Definition

The Global Reporting Initiative (GRI) is a non-profit organization, established in 1997, which issues guidelines for companies to follow when

drawing up sustainability reports. GRI Standards represent the global best practice for reporting on a range of social, economic, and environmental impacts of business.

Introduction

GRI is an international NGO that provided the first globally accepted framework for comprehensive sustainability reporting. The aim of the initiative is to promote Corporate Social Responsibility (CSR) through publishing guidelines for producing voluntary sustainability reports worldwide. A quarter of a century ago, it would have been almost unthinkable for listed companies to be pressured into reporting on their economic, social, and environmental impacts since sustainability reporting was then not widely practiced. Since that time, CSR has become mainstream and sustainability reporting has become common practice. Moreover, GRI's founding of sustainability issues has become a mainstream area for every stakeholder. According to a recent study, more than 90% of the world's largest companies issue sustainability reports and 75% of them are using the GRI schema. Through its support on reporting the GRI, it has helped to identify and report the sustainability impacts of many companies which provided benefits to countless people and the environment. Today, shareholders are pushing for increased CSR reporting. In 2017, more than half of shareholder resolutions involved requests for more ESG information (Eccles, and Klimenko 2019).

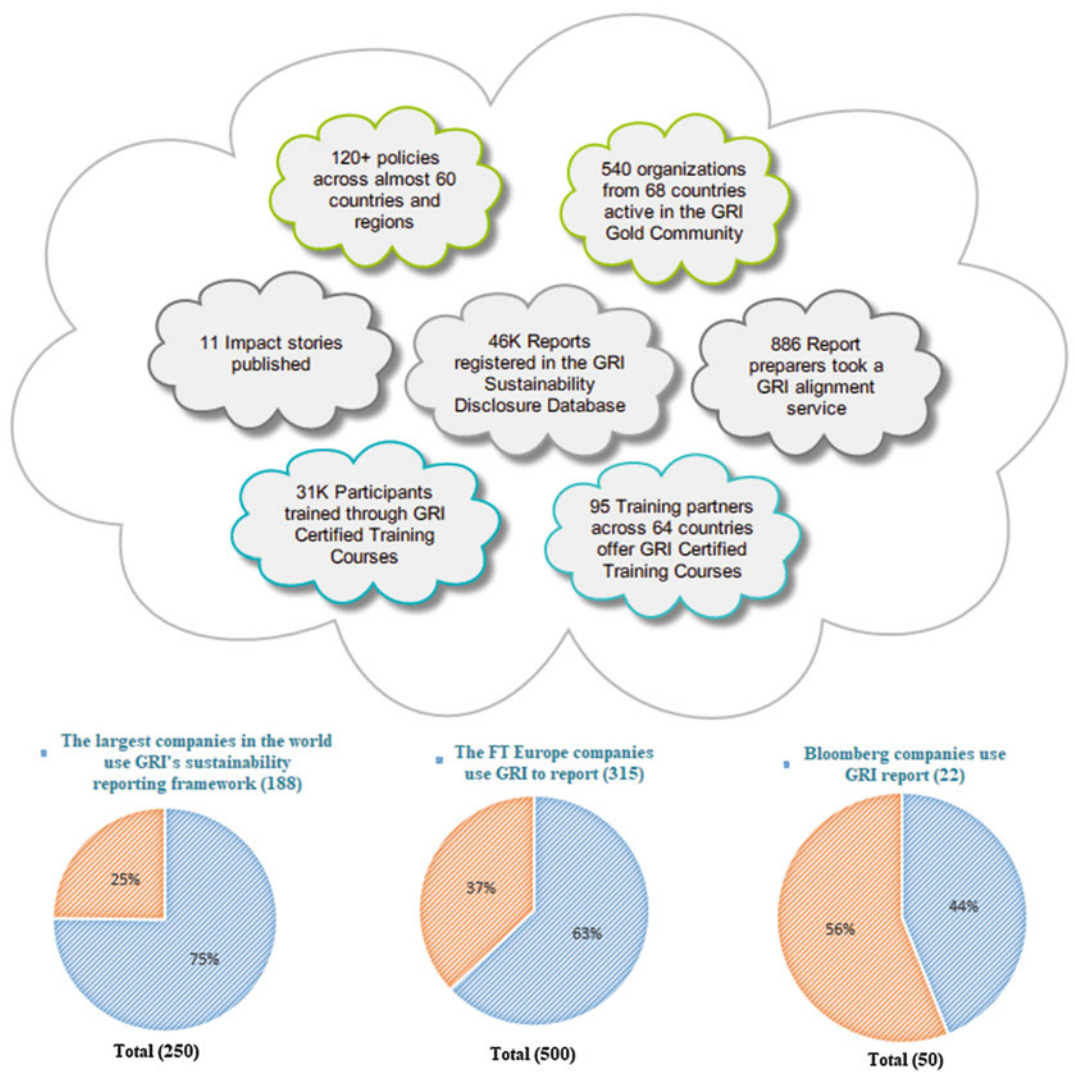

GRI emerged during the 1990s to coordinate pressure on companies to make reporting common practice. It was established in 1997 in Amsterdam by the Coalition of Environmentally Responsible Economies (CERES) in collaboration with the UN Environment Programme (UNEP), through an alliance of multinational companies, NGOs, labor organizations, academics, and environmental organizations – but not including governments (Carroll and Buchholtz 2009). GRI itself is an independent international organization that issues guidelines for companies to follow when drawing up

sustainability reports. Sustainability reports are those reports which organizations publish information on their economic, environmental, social, and management performance (being either GRI-based, GRI-referenced, or non-GRI reports).

GRI, as an international initiative, is an important step for the further development of CSR. Although there is no single, global definition of CSR, it has been described as a voluntary interaction in 2001 (EU Commission Green Paper 2001), and then the EU revised its definition and accepted as a responsibility of enterprises regarding their impacts on society (Turker 2018, p. 5) (EC 2012). A new, more widely accepted definition of CSR is as “a private self-regulatory scheme” (Sheehy 2015, p. 628). According to Sheehy, CSR can be treated as a type of international private law or private self-regulatory initiative. This institutional definition highlights the rules, norms and beliefs, and the actors involved in those institutions (Sheehy 2015, p. 639). From that point of view, if the CSR is an effort to regulate industrial organizations' decisions and objectives for purposes of lessening industrial harms and increasing public welfare, it needs a regulatory infrastructure or a framework to create and adjudicate the rules (Sheehy 2019). The Global Reporting Initiative (GRI) is an organization which serves as infrastructure to institutionalize the norms by collecting, classifying and describing, and disseminating them among industry, and the participants are expected to modify their behavior to conform to those norms (Sheehy 2015, p. 639).

Today, 93% of the world's largest 250 organizations report on their sustainability performance. In this context, GRI Sustainability Reporting Standards (GRI Standards) have become the most widely used sustainability disclosure standards worldwide. According to GRI, 13,353 organizations produced 52,623 sustainability reports, of which 31,727 used the GRI standards (Fig. 1, GRI, 2019).

GRI's explicit goal was “to harmonize the numerous environmental and sustainability reporting systems at the time and create free access to standardized, comparable and consistent information about corporate performance” (Toker 2015). A GRI report contains “50 core

Global Reporting Initiative, Fig. 1 GRI in numbers (2019). (Adapted from GRI web site 2019)

environmental, social, and economic indicators with distinct metrics for companies, depending on their industry sector and operations” (Szejnwald 2011). The cost of producing a sustainability report ranges from \$100,000 for a basic GRI to more than \$3 million for complex organizations such as Shell or Nike (Luftig and Ouellette 2012). When the company uses the GRI-reporting structure, they need to use the GRI Sustainability Reporting Framework and GRI Content Index, which consists of A, B, and C levels (report types: G3, G3.1, G4, and GRI Standards) (GRI 2017).

The Measures and Key Elements of GRI

The first official edition of GRI Guidelines was released in June 2000. In total, 31 companies piloted tests of the Guidelines. The second GRI edition soon followed after an international symposium which gathered labor, international NGOs, and investors from all over the world. It was used to create a global multistakeholder network. In 2002, a second edition of the Guidelines (G2) was released at the World Summit on Sustainable Development. In 2006, the third

generation of Guidelines (G3) was released (Brown et al. 2007).

There are four key elements in GRI framework:

- Sustainability-reporting guidelines include principles and performance indicators for defining report, content, and quality. The third edition of the Guidelines – the G3 – was published in 2006.
- There are performance indicators in the guidelines which include definitions and other information to assist report writers and to ensure consistency in the interpretation of the performance indicators.
- Sector supplements complement the guidelines with defining sector-specific performance indicators.
- Technical protocols are providing guidance on the boundary of the report.

GRI has had significant advances in recent years converting from guidelines to standards in 2016. These standards are an evolution of the GRI G4 Sustainability Reporting Guidelines, which were released in 2013, and have since been widely adopted. Changing the GRI “Reporting Guidelines” to “Standards” indicates a higher level of specificity and allows greater rigor in reporting activities. In addition, GRI adopted a new modular approach for easier updates. By 2017, GRI Standards included GRI 303, GRI 403, GRI 201, and GRI 306 (Fig. 2).

GRI is also working closely with companies to support the reporting process, and provide data for researchers. In order to improve the quality of this process, GRI certified 17 software tools providers in 2017 to accurately incorporate GRI Standards into their various reporting tools (GRI 2017).

There are ongoing developments that show an increasing interest in sustainability reporting and GRI Standards in the business world. For example, launching an Arabic translation of the GRI Standards allowed sustainability reporting to be more accessible to companies reporting in that language. Additionally, the GRI Standards are

also integrating sustainability reporting with the goals of GSD. Moreover, GRI and the UN Global Compact established close partnership on empowering businesses to prioritize SDG goals. This move allows companies that work with GRI to not only map their efforts onto SDGs but also contribute more holistic approach for the accomplishment of these goals.

Summary

The Global Reporting Initiative (GRI) is an independent institution to develop and disseminate globally accepted sustainability reporting guidelines for organizations on their social, economic, and environmental activities or products. It has spent the past 20 years providing a framework for companies to report social, economic, and environmental standardized performance.

GRI has become the blueprint for organizations to define, report, and improve their sustainability programs. The ultimate aim of developing and using GRI Standards is to contribute to a sustainable global economy via globally accepted credible reporting standards. This greater transparency will empower the companies, their stakeholders, and shareholders to make better decisions to achieve global sustainability.

Today the question is no longer whether companies should report but what they should be reporting on. The aim is to make the industry sustainable better aligning capital with the global sustainability agenda. GRI supports organizations worldwide that communicate and understand their impacts on critical sustainability issues, such as climate change, human rights, governance, and social well-being. This level of awareness leads to action that can create social, economic, and environmental benefits for everyone.

Definition

The Global Reporting Initiative (GRI) is one of the world's most influential nonprofit organizations that publishes guidelines on nonfinancial information. GRI defines itself as a pioneer of sustainability reporting, and it has largely contributed to enhancing the quality and diffusion of this kind of reporting in both developed and emerging countries since the end of the twentieth century.

GRI firmly believes that fair, effective, and transparent reporting on the economic, social, and environmental performance of an organization produces broad benefits for the organization itself, but also for its stakeholders and society at large.

For this reason, GRI performs varied and complex activities, supporting organizations that are committed to sustainability reporting. In addition to its main activity as a globally recognized standard-setter, GRI encourages dialogue on sustainability reporting through conferences, summits, and strategic partnerships. Moreover, GRI offers chargeable services to individual organizations and professionals involved in the sustainability reporting process.

Introduction

The Global Reporting Initiative (GRI) is an international organization that provides companies and other entities with guidance for the proper preparation of sustainability reports (Herriott 2016).

According to GRI, an entity that regularly draws up and publishes sustainability reports can better understand the various risks to which it is subject, the opportunities to be seized and the link between financial and nonfinancial performance, with a consequent improvement in the long-term strategic planning. Moreover, an organization devoted to sustainability reporting can more easily compare its performance with the laws, regulations, and voluntary codes concerning the social and environmental impacts of corporate activities. This also prevents the organization from being involved in social, environmental, and corporate governance failures. In addition, systematic sustainability-reporting processes strengthen the corporate reputation and build trust.

From a stakeholder's perspective, sustainability reporting fosters a better knowledge of entities' ethical principles, vision, mission, and goals, and it supports a deeper appreciation of their performance, including social and environmental. For all these reasons, sustainability reporting has the power to channel financial resources toward the organizations that can most likely use them in the most profitable and equitable way.

GRI adopts a multistakeholder approach in all phases of its standard-setting activity, from the initial proposal of a standard to its final approval. This has certainly contributed to enhancing GRI's reputation in the international arena. Therefore, we have witnessed an increasing adoption of the 2016 GRI Standards in all kinds of companies, from multinational and large firms to SMEs, operating in advanced economic systems as well as in developing ones.

The GRI Standards have replaced various generations of GRI Guidelines. The GRI Standards build on the "in accordance" principle and the materiality analysis (Torelli et al. 2020; Beske et al. 2020; Safari and Areeb 2020), which were already proposed in the previous Guidelines, known as G4 (Slacik and Greiling 2019). Since the introduction of the G4, companies must comply with the "in accordance" principle, which allows the adoption of the "core" option or the "comprehensive" one in order to report with different levels of detail. In any case, a materiality analysis is required to identify significant issues to

be discussed in the report. However, the shift from the G4 Guidelines to the GRI Standards determined important changes too. Among others, the GRI reporting principles concerning the report content and quality became mandatory. On the contrary, the introduction of the GRI Standards made the use of specific Sector Standards only recommended, in spite of the compulsory nature of the former Sector Guidelines. In fact, the application of a Sector Standard is now mediated by the materiality principle, which not only provides companies with a wider margin of discretion, but also increases their responsibility for the implemented reporting choices.

GRI also manages a Sustainability Disclosure Database, where it collects all types of sustainability reports. In August 2019, the Database hosted over 55,500 reports from nearly 14,000 organizations, and 60% of those documents (i.e., approximately 33,000) were GRI reports.

GRI's activity also includes a range of report services, the organization of global and local events, and the development of projects alongside prestigious partners. All these activities are run by the staff employed at the GRI headquarters in Amsterdam, the Netherlands, and in the regional hubs and offices around the world. In 2018, GRI had little more than 100 employees (GRI 2018a).

GRI is a global network that can rely on several sources of funding, including corporate sponsorship of events and project grants from governments and foundations. Moreover, GRI finances itself through the sale of report services and the collection of fees and donations from its Community members. The GRI Community comprises approximately 600 companies, governmental and nonprofit entities, consultancy and accountancy organizations, rating agencies, academia, and research institutes.

The History

GRI was founded in Boston in 1997 on the initiative of two American nonprofit organizations – the Coalition for Environmentally Responsible Economies (CERES) and the Tellus Institute – that encouraged investors and companies to

consider social and environmental issues in their decision-making processes. Originally, GRI operated as a project department of CERES with the mandate of developing a framework for environmental reporting. The framework should have supported an accountability mechanism to enable investors to verify whether the companies declaring to adopt the CERES Principles for responsible environmental conduct were indeed respecting them (GRI [n.d.](#)).

In 1998, GRI introduced a multistakeholder Steering Committee, which recommended the inclusion of social, economic, and governance issues in the scope of the framework. A broader interest in sustainability therefore began to replace GRI's initial focus on the environment. Soon after, GRI launched the first edition of its *Sustainability Reporting Guidelines* (2000), the core of its reporting framework.

In 2001, GRI was separated from CERES, and in the following year, it was relocated to Amsterdam where it was established as a “*stichting*,” the Dutch word for a nonprofit foundation. Moreover, GRI received formal recognition as a UNEP-collaborating organization during an event in the presence of Kofi Annan, then UN Secretary General. In 2002, the second version of the GRI Guidelines (“G2”) was also presented at the UN World Summit on Sustainable Development in Johannesburg.

The year 2003 was a milestone year for GRI, which enhanced stakeholder dialogue and cooperation. On the one hand, GRI introduced an Organizational Stakeholders Program, allowing its core supporters and funders (including companies, civil society, mediating institutions, academia, the workforce, and public and intergovernmental agencies) to contribute to GRI governance with their expertise and experience in sustainability matters and sustainability reporting. On the other hand, a new governance body called the Stakeholder Council started to operate as a multistakeholder forum in charge of advising the Board of Directors about strategic issues.

Three years later, GRI published the third generation of its Guidelines (“G3”), the development of which had required a multistakeholder approach involving over 3000 experts from

businesses, civil society, and the workforce. The G3 Guidelines were launched during GRI's Global Conference on Sustainability and Transparency in Amsterdam, the first in a series of events that since then has gathered participants from all over the world, including emerging markets. Four other Global Conferences were organized in 2008, 2010, 2013, and 2016 after the success of the first one, attracting thousands of experts in sustainability reporting, practitioners, and representatives of different stakeholder groups to the Dutch capital.

In the meantime, the growing demand for information about a company's social and environmental impacts and the need for comparable reports led to the establishment of GRI focal points – today known as regional hubs – in all the continents. In order to improve sustainability reporting at country level, reach more potential users of Guidelines, and better understand the information needs of local report users, GRI set up offices in Brazil (2007), Australia (2008), China (2009), India (2010), the USA (2011), South Africa (2013), and Colombia (2014).

In addition, GRI published several Sector Supplements to the basic Guidelines. In doing so, GRI intended to provide organizations from specific industries with highly focused guidance, to help them divulge better-structured information on how they had faced the typical social and environmental issues of their sector. Over the years, Sector Supplements have been issued for Financial services (2008), Electric utilities (2009), Food processing (2010), NGOs (2010), Mining and metals (2011), Airport organizations (2011), Construction and real estate (2011), Oil and gas (2012), Media (2012), and Event organizers (2012).

Further topics concerning gender and human rights were also added to the GRI Guidelines in 2011, when an improved edition (“G3.1”) was released. In the same year, GRI inaugurated a Sustainability Disclosure Database to collect any kind of sustainability report, both GRI- and non-GRI-based.

In 2012, GRI actively participated in the work of the Rio+20 United Nations Conference on Sustainable Development, promoting several side

initiatives. Moreover, GRI cooperated with UNEP as secretariat of the Group of Friends of Paragraph 47, a multigovernment network that aimed to enhance the disclosure of corporate sustainability information.

In 2013, GRI issued the fourth version of its Guidelines (“G4”) (Jones et al. 2016; Kumar et al. 2018; Mori Junior and Best 2017) and launched a free web-based tool (“G4 Online”) presenting the Guidelines’ content in a dynamic format.

The year 2014 can be considered a turning point in GRI’s history, due to a profound transformation of its governance. GRI separated the standard-setting function from fundraising and all other activities. The former was attributed to the newly established Global Sustainability Standards Board (GSSB), whereas the latter remained under the responsibility of the Board of Directors. Other governance bodies were also established with the aim of assuring the independence of the standard-setting body, greater transparency, and broader representation of all GRI’s stakeholders.

The first significant achievement of this dual governance structure was the release of an advanced framework for sustainability reporting, namely the GRI Standards, in October 2016 (Gallego-Álvarez et al. 2018; Parsa et al. 2018). The Standards, which had been prepared by the GSSB and submitted to public consultation, have a modular structure and present greater flexibility, clearer requirements, and simpler language than the previous Guidelines.

Finally, the most recent years have been characterized by a significant engagement of GRI with the United Nations Global Compact (UNGC) to improve the reporting on the Sustainable Development Goals (SDGs). In September 2016, GRI and UNGC signed an agreement to colead an Action Platform, supported by the Principles for Responsible Investment (PRI), in order to accelerate corporate reporting on SDGs. The major players of the global investment community, who had convened in Stockholm in May 2017, warmly welcomed the Action Platform. This project also opened the way to several reporting tools for measuring a company’s performance in light of the SDGs. Among others, GRI and UNGC published the following:

- “Analysis of the Goals and Targets” (September 2017)
- “In Focus: Addressing Investor Needs in Business Reporting on the SDGs” (July 2018)
- “Integrating the SDGs into Corporate Reporting: A practical Guide” (August 2018)

Mission and Focus Areas

GRI has a vision: “a thriving global community that lifts humanity and enhances the resources on which all life depends” (GRI 2018a). To make all of this happen, the GRI’s mission is “to empower decisions that create social, environmental and economic benefits for everyone” (GRI 2018a).

To accomplish its mission, GRI has determined four strategic pillars or focus areas (GRI 2018a):

1. Production of standards and guidance to advance sustainable development, also promoting stakeholder engagement on emerging issues.
2. Harmonization of the sustainability landscape in the effort to become the reference point for sustainability reporting, also through cooperation with other organizations.
3. Efficient and effective sustainability reporting, marked by higher quality of the information divulged and less burden on the reporting organizations.
4. Collaboration with all third parties (e.g., policy makers, regulators, stock exchanges, and investors) to enhance transparency and promote a widespread and effective use of sustainability information.

GRI is also aware of its vast potential as an agent of change toward the achievement of the SDGs (GRI 2016a). Through the continuous improvement of its sustainability reporting standards, GRI intends to support the fulfillment of the 2030 Agenda by helping the private sector make better-informed decisions, based on a balanced consideration of social, economic, and ecological aspects. The final purpose of GRI is to contribute to a more inclusive and greener economy, in which companies may positively affect civil

society and the environment, particularly in developing countries and in relation to the emerging challenges that humanity faces.

In the context of the 2030 Agenda, GRI has chosen to cooperate with the UN and other international organizations to achieve *Target 12.6*, established within *Goal 12* on Responsible Consumption and Production. In fact, Target 12.6 encourages companies, especially large and transnational ones, to adopt sustainable practices and to integrate sustainability information into their reporting cycle.

Finally, GRI is committed to drawing the attention of policy makers, regulators, and corporations toward the following issues: human rights, climate change, good governance and anticorruption, SMEs, trade facilitation and sustainability, capital markets, and gender equality.

Structure of Governance

GRI has a dual governance structure, which was approved in October 2014 after the appointment of Michael Meehan as Chief Executive. Through the reform of its governance structure, GRI aimed to ensure the complete independence of its standard-setting process. Independence is a strict

requirement for GRI to be accepted by regulators and in all relevant forums as a public reporting standard-setter (GRI 2014). For this reason, in GRI’s reformed governance the Board of Directors delegates the authority to develop and approve the reporting Standards to an independent and dedicated body, the Global Sustainability Standards Board (GSSB). All other activities remain under the responsibility of the Board of Directors.

The governance reform has also safeguarded the global multistakeholder principle, one of GRI’s essential and long-standing features. In other words, GRI recognizes the key role of stakeholders in all strategic decisions, including the appointment of its most important bodies. Moreover, full transparency in all governance processes is guaranteed to GRI’s stakeholders and the whole audience.

Figure 1 shows the dual governance structure currently in force. GRI’s governance is based on two subsystems, which are separated by an organizational firewall established between the bodies involved in the standard-setting process and those responsible for all other activities. This official separation avoids interference between the bodies forming each subsystem, although the two subsystems must interact according to a specific protocol.

Global Reporting Initiative Standards, Fig. 1 GRI dual governance structure. (Source: Adapted from *GRI Annual Report 2016–2017*, p. 40)

Each subsystem comprises bodies with different powers and tasks, such as appointment of members, strategic decision-making, administration, daily management of operations, and oversight. Furthermore, the composition of each body should guarantee the representation of stakeholders of a different nature and geographical origin, according to the multistakeholder approach that lies at the core of GRI's governance philosophy.

All governance bodies have a 3-year mandate, which is usually renewable once for another 3-year term; however, one-third of the members must be replaced (or reelected) every year. All members serve on a voluntary basis, with the sole exception of reimbursement for travel expenses.

In GRI's dual governance structure, the Board of Directors and the GSSB remain at the top of the two subsystems.

The *Board of Directors* is GRI's highest governing body, with administrative powers and oversight responsibilities (GRI 2018b). It determines GRI's mission and purpose, approves strategies and business plans, selects the Chief Executive (normally from its own members), supports them and reviews their performance. The Board also ensures the effective functioning of GRI's organizational structure; in particular, it is responsible for finding the financial resources necessary for the organization to operate and for verifying their prudent and efficient use. Moreover, the Board oversees internal control procedures and external auditing. Finally, it interacts with other governance bodies, including the GSSB to which it provides input and advice on relevant matters. The Board must meet at least twice a year.

The Board of Directors is appointed by the *Stakeholder Council* (SC). The SC is a formal multistakeholder forum that also advises the Board and the Chief Executive on strategic issues and makes broad recommendations on GRI's future policy (GRI 2016b). The SC comprises up to 50 members in representation of all regions of the world (East Asia and Pacific, Europe and Central Asia, Latin America and the Caribbean, Middle East and North Africa, North America,

and South Asia and Sub-Saharan Africa) and all constituencies (i.e., stakeholder categories). More exactly, the SC is composed of the following constituencies:

- *Business enterprises*, which hold 40% of seats
- *Investment institutions*, such as asset owners and managers, development banks, stock exchanges, and rating agencies, which have the right to occupy 15% of seats
- *Labor organizations* (e.g., trade unions), which are entitled to 10% of seats
- *Mediating institutions*, such as consultants, assurance providers, and any other expert and organization providing reporting-related services, which hold 20% of seats
- *Civil society organizations* engaged in social, environmental, and governance issues, which cover 15% of seats

Evidently, each constituency may contribute to the debate on sustainability-reporting priorities and the need for transparency with different perspectives. Similarly, specific concerns tend to arise in diverse regional contexts and deserve to be discussed during the SC meetings. In order to make sure that all the positions and views are fairly considered, the SC charter states that each constituency should include at least one representative from each geographic area of the world.

The SC, which meets in person at the annual general meeting and may have further video- and teleconferences, supports the mission of GRI by taking active part in its sponsored events.

The election of the SC is a complex process, which is managed in a transparent, open, and objective way by a devoted governance body, namely the *GRI Nominating Committee* (GNC). The composition of the GNC is mixed, as it comprises the chair and two other members of the Board of Directors, and the chair and two other members of the SC currently in office, for a total of six members. The GNC identifies possible candidates to the SC and recommends their appointment in representation of the SC constituencies. In this regard, the GNC makes its recommendations to:

- The Organizational Stakeholders, also known as the *GRI GOLD Community* and corresponding to GRI's core supporters
- The SC itself, given that only one-third of the body is up for consideration on an annual basis

The procedure involves two phases. In the first phase, the *GRI GOLD Community* nominates 60% of SC members. In this phase, each *GOLD Community* member votes for a candidate from their own constituency. In the second phase, the SC itself appoints the remaining 40% of SC members, regardless of constituency.

The governance subsystem centered on the Board of Directors is completed by the *Secretariat*, an executive team based in Amsterdam. The Secretariat manages GRI's activities in order to implement the Board's strategic plans and the SC's recommendations. The team is led by the *Chief Executive*, who is also a member of the Board and supervises all operations. At present, management processes are carried out in five departments:

- *Operations*: The department is in charge of day-to-day management, with focus on human resources, finance, information technology, and governance.
- *Reporting Standards*: The department is responsible for maintaining, developing, and enhancing GRI's Sustainability Reporting Framework.
- *Development*: The department is entrusted with the implementation of GRI's funding strategy and partnerships with donors, and it receives reports from GRI's regional hubs around the world.
- *External Affairs*: The department is charged with GRI's communication strategy and external relations.
- *Network Engagement*: The department has broad responsibility in relation to report services, training and coaching, stakeholder relations, and coordination of regional hubs.

The second governance subsystem relates to GRI's standard-setting activity, which falls under the remit of the *Global Sustainability Standards*

Board (GSSB). This is an independent entity introduced by the governance reform of 2014 and established under the auspices of the Board of Directors. The sole responsibility of the GSSB is to prepare and approve generally accepted standards for sustainability reporting and their interpretations in the public interest. In the context of sustainability reporting, serving the public interest means promoting transparency on social, environmental, and economic matters and providing guidance that can adequately support informed decision-making.

According to the GSSB Terms of Reference (GRI 2018c), the body shall be composed of 15 members drawn from all the GRI constituencies: 5 members from business enterprises and 2 from each of the other stakeholder groups, in addition to 2 eminent persons to hold the positions of Chair and Vice-Chair. All GSSB members shall be chosen according to their professional competence, practical experience and awareness of the sustainability reporting environment, ability to analyze issues, communication skills, integrity, objectivity and discipline, and commitment to GRI's vision and mission (GRI 2015).

Several rules and procedures aim to preserve the necessary independence of the GSSB.

First, nobody shall simultaneously hold positions in the GSSB and another GRI governance body; in addition, a period of 12 months shall elapse before an individual who has already served in other GRI governance bodies becomes eligible for the GSSB.

Second, a public funding base – separate from those of all other GRI activities – is reserved to the GSSB to protect it from vested interests.

Third, the members of the GSSB are selected and nominated by a qualified *Independent Appointments Committee* (IAC), which is made up of 5 members with high reputation, undisputable integrity, and solid background in sustainability reporting. In turn, the IAC is appointed by the so-called *Extended GNC*, including the 6 members of the GNC and 3 external experts from the field of international standard-setting (e.g., IOSCO, ILO, and UNEP) (GRI 2015).

Fourth, in the fulfillment of its tasks the GSSB must strictly adhere to a *Due Process Protocol* that safeguards the quality of the whole standard-setting process in the public interest and emphasizes the multistakeholder approach. The Protocol regulates the creation and release of GRI *Standards* and their *Interpretations*, which are cumulatively defined authoritative pronouncements of the GSSB. The process involves not only the GSSB, but also the GRI Board of Directors and Stakeholder Council, both in an advisory capacity. In addition, the GSSB may create temporary *Technical Committees* and *Project Working Groups* to obtain technical consultations. The entire procedure is supervised by the *Due Process Oversight Committee* (DPOC), which is appointed by the IAC and comprises five senior individuals of high reputation and expertise in sustainability reporting. More precisely, the DPOC provides assurance that the standard-setting activity has been conducted in full compliance with the Due Process Protocol, thus strengthening the confidence of policy makers, investors, and the general audience to the GRI Standards (GRI 2016c).

Activities and Major Accomplishments

GRI is mainly known for its internationally recognized standard-setting activity in the field of sustainability reporting. However, GRI runs many other activities and provides services to a number of organizations, as described below.

Standard-Setting Activity

GRI's standard-setting activity is carried out by the GSSB, in accordance with the Due Process Protocol that imposes the following steps (GRI 2018d):

1. *Project identification and prioritization.* The GSSB identifies potential new projects, taking account of recommendations and comments from the Board of Directors, the SC, and other entities interested in a reporting standard. However, such views are not binding for the GSSB.
2. *Project commencement.* The Standards Division prepares a project proposal, based on a consultation within the GSSB. The GSSB can approve, modify, or reject the proposal, which is also presented to the Board of Directors and the SC in order to collect their opinions on the matters included in the project.
3. *Formation of technical committees and project working groups.* The GSSB may establish Technical Committees and Project Working Groups to obtain technical advice on significant matters. Such bodies are only temporary, and their composition should respect the multi-stakeholder principle.
4. *Development of proposed standard.* The GSSB is entitled to hold a roundtable, submit the proposed Standard to a public consultation, or even carry out a field test. Members of the GSSB who vote for an exposure draft demonstrate their satisfaction with the proposal.
5. *Public exposure.* An approved draft Standard is submitted to public comment through its publication on the GSSB website for at least 60 days. Anyone can access the draft Standard free of charge; moreover, all opinions and suggestions must be recorded and divulged on the GSSB website.
6. *Consideration of respondents' comment on an exposure draft.* The GSSB must analyze all comments and use them to decide whether the draft requires a revision or even further exposure.
7. *Approval of standard or reexposure.* The final revised version of the Standard is approved by the GSSB. The GSSB may also submit the revised content to a new exposure, clearly explaining the reasons for this.
8. *Release of final standard.* The process is completed when the GSSB issues the final Standard. To proceed with this final step, the Chair of the GSSB shall inform the DPOC that the whole process has been conducted according to the Due Process Protocol, and it shall obtain a positive response from the DPOC.

As summarized in the History section, GRI had released four generations of Guidelines before introducing the GRI Standards. These latter were

issued in October 2016 and became the solely accepted ones for the reports published from 1 July 2018 onward.

The GRI Standards consist of a set of modular, interrelated standards, each of which can be revised and updated by the GSSB separately from the others. The Standards are classified in the following series:

- The *Universal series* (GRI 100), which comprises 3 Standards. These Standards explain how to use the Standards, identify the information to be disclosed with reference to the company's profile, strategy, ethics and integrity, governance, stakeholder engagement practices, and reporting process, and require the description of how the company manages material topics.
- The *Economic series* (GRI 200), which includes 6 Standards. These Standards concern information such as the company's economic performance, market presence, and anti-corruption practices.
- The *Environmental series* (GRI 300), which is composed of 8 Standards. These Standards focus on the disclosure of the company's impact on natural resources (in terms of materials, energy, water, biodiversity, emissions, and waste) and supplier environmental assessment.
- The *Social series* (GRI 400), which contains 19 Standards. These Standards regulate the disclosure of information on labor topics (employment, labor relations, training, occupational health and safety, equal opportunities, and child and forced labor), human rights and local community matters, customer health and safety, and supplier social assessment.

Each company is expected to report "in accordance" with the Standards, selecting between the "core" option, which supports the preparation of a less detailed report, and the "comprehensive" option, which results in an in-depth report. Regardless of the option selected, the company will only disclose information on material matters, i.e., those reflecting the significant economic, environmental, and social impacts of the

company's activity and that substantively affect stakeholders' decisions.

Similarly to the previous Guidelines, the GRI Standards have maintained a sustainability-reporting framework based on principles for defining the content of sustainability reports (stakeholder inclusiveness, sustainability context, materiality, and completeness) and ensuring the quality of the information disclosed (accuracy, balance, clarity, comparability, reliability, and timeliness).

Conferences and Summits

GRI organizes conferences and summits to meet its stakeholders and encourage dialogue on sustainability reporting. Thanks to the increasing popularity of GRI over the years, such events have attracted thousands of participants from all over the world, also offering valuable opportunities for networking and learning in an inclusive context. Since 2006, GRI has hosted five global conferences in Amsterdam to discuss the emerging issues in sustainability and understand the contribution of sustainability information to the improvement of corporate strategies. Moreover, in 2012 the GRI hubs in Australia, North America, and South Asia started to organize regional conferences and summits. Figure 2 presents GRI's main events from 2006 to 2019.

Services Offered to Reporting Organizations and Professionals

GRI offers a wide range of chargeable services to support the preparation of sustainability reports. In doing so, GRI contributes to the improvement of information quality and usability to meet the public interest.

GRI has established a Certified Training Program. In the last decade, over 250 training sessions were attended by nearly 35,000 participants in Europe, the Americas, Africa, Asia, and Oceania (GRI 2019).

The Certified Training Program includes face-to-face courses provided in local languages by selected partners, who also discuss local case studies. The courses can be basic or advanced: While the basic courses ensure an essential knowledge of GRI Standards, the advanced

Global Reporting Initiative Standards, Fig. 2 GRI conferences and summits. (Created by this Author)

courses focus on specific topics (such as materiality and stakeholder engagement).

GRI offers e-learning programs too. These are designed for a wider audience, including all those who want to acquire an introductory knowledge and understanding of sustainability reporting and GRI Standards, but do not need an official certification.

Another learning opportunity consists in one- or two-day tailored seminars arranged for small groups, such as managers and employees of a company's sustainability department.

Individuals who want to demonstrate their knowledge of the GRI Standards, particularly after participation in a Certified Training Program, can take an exam online. Successful candidates receive a 3-year Certificate of Achievement, and their names are listed on the GRI website.

GRI has also created software applications and tools, such as the Digital Reporting Tool, to make the collection of information easier for the reporting organizations and ensure the publication of more robust and transparent reports.

On request, GRI provides several report services like content feedback, Standards alignment test, and process support. An organization can pay for the Disclosure Review Service, through which GRI checks the content of its sustainability report and gives recommendations about the necessary adjustments to align it with the Standards. This service usually covers stakeholder engagement and materiality sections and the disclosure of the management approach to sustainability. In addition, a company can request a Published Report Review Service, which is conducted by GRI staff members as an exclusive seminar.

Strategic Partnerships

GRI has set up partnerships and alliances with other organizations that believe in the importance of fair and transparent reporting for inclusive and sustainable growth. As this also corresponds to Target 12.6 of the 2030 Agenda on SDGs, one of the most recent partnerships undertaken by GRI has led it to cooperate directly with the UN. However, many other effective collaborations between GRI, governmental, and nonprofit institutions have already taken place in previous years.

Since 2010, GRI has collaborated with OECD to spread the combined adoption of OECD's Guidelines for Multinational Enterprises, which provide guidance on sustainable practices, and GRI's reporting framework. In OECD's view, as well as in GRI's, the disclosure of nonfinancial information is indeed a key factor of sustainable development worldwide.

GRI has also a long history of working with the UN Global Compact (UNGC), which dates back to 2010 when the two organizations signed a Memorandum of Understanding. Since then, GRI's reporting framework has been officially accepted for the preparation of the UNGC annual Communication on Progress, a document that demonstrates an entity's commitment to the Ten Principles of the Global Compact.

GRI and UNGC have also signed an alliance with the Earth Charter Initiative, with the purpose of building a just, sustainable, and peaceful global society in the twenty-first century.

GRI's partnership with the United Nations Environment Programme (UNEP) started in 2002 and led to two major outputs: the GRI Financial Services Sector Supplement (2008) and an annual study on global trends in sustainability-reporting regulation and policy, titled "Carrots and Sticks."

GRI took also part in the development of ISO Guidance Standard on Social Responsibility (ISO 26000), released in November 2010. Shortly after the issue of ISO 26000, GRI published a document to highlight the link between the social responsibility areas considered in Guidance and the need for transparency.

With reference to the disclosure of information on corporate environmental performance, GRI has joined efforts with CDP (previously known as Corporate Disclosure Project). Since May 2013, the organizations have cooperated to make their reporting tools more usable for companies, in order to prevent duplication of information on the impacts of climate change, water consumption, air pollution, etc.

Furthermore, GRI has established a partnership with the International Finance Corporation (IFC), the largest global institution focused on the private sector in developing countries. The

partnership aims to raise awareness on the necessity of transparency in the private sector's organizations. Moreover, it intends to encourage investment in companies that adopt the best corporate governance practices and have achieved valuable social and environmental performance.

Fair and equitable growth of developing countries is also at the core of GRI's collaboration with the United Nations Conference on Trade and Development (UNCTAD). Launched in 2008 and then renewed in 2017, this alliance focuses on responsible investment and the global value chain.

Furthermore, GRI and its most important partners (including UNCTAD, UNGC, UNEP Finance Initiative, and the Principles for Responsible Investment) support the Sustainable Stock Exchanges (SSE) Initiative. The SSE Initiative is a worldwide multistakeholder platform that involves stock exchanges, regulators, and investors and encourages listed companies to disseminate well-structured nonfinancial information to the markets.

GRI's strategic partners also include governments, multilateral donors, and foundations, which have provided GRI with significant financial support in this decade. Among others, GRI has run programs funded by the Swedish International Development Cooperation Agency (SIDA), the Swiss State Secretariat for Economic Affairs (SECO), the UK Department for International Development (DFID), the Australian Department of Foreign Affairs and Trade (DFAT), the Robert Wood Johnson Foundation, the Alcoa Foundation, and the Spanish Fundación ONCE.

Summary

In over 20 years of activity as an internationally recognized standard-setter, GRI has largely contributed to the global diffusion and continuous improvement of sustainability reporting.

GRI's success is mainly attributable to two main factors: the multistakeholder approach that GRI adopts in the production of sustainability reporting standards, on the one hand, and the

strong independence and transparency characterizing its whole work, on the other.

Since the beginning of this century, the growing interest in sustainability matters and non-financial reporting has resulted in the establishment of a number of GRI's regional hubs around the world and in a wide range of services provided to organizations and professionals. Indeed, GRI has systematically encouraged and accompanied thousands of organizations in the preparation of their sustainability reports, which have become increasingly complete, effective, and reliable. Moreover, GRI has supported professionals determined to improve their knowledge and expertise in sustainability reporting practices.

Thanks to GRI's valuable efforts, sustainability reporting enables a greater understanding of the mechanisms that organizations use to properly balance their economic performance and social and environmental concerns.

Global Value Chains

Ignacio Llorente, Maria D. Odriozola and Elisa Baraibar-Diez

Business Administration, University of Cantabria, Santander, Cantabria, Spain

Synonyms

Cross-national value chains; Global supply chains; GSCs; GVCs

Definition/Description

The value chain represents the set of activities necessary to manufacture a good or service, each of which generates added value to the product, which represents a more strategic management approach. The concept of Global Value Chains (GVCs) represents the international extension of this definition. GVCs focus not only on the firm competitiveness, as the value chain theory aims, or the movement of final products, as classical international trade theories have analyzed, but on the cross-national transfer of tasks, having special relevance to the value added or generated by these tasks. GVCs and their role in the economic performance of countries, industries and firms have been extensively discussed in the management and economics literature.

Introduction

Since Mikel Porter first presented the concept of value chain (Porter 1985) as a basic framework for developing a corporate strategy to promote firm competitiveness, the conception has significantly evolved to new dimensions beyond the firm, thanks to the globalization and the new industrial revolution based on technology and information.

The advances in transports and communication technologies and the reduction of trade barriers facilitated and fostered international trade, based on faster, cheaper, safer, and more efficient

Global Supply Chains

► Global Value Chains

transactions, which led to globalization. The term globalization, although widely used and difficult to conceptualize, can be summarized in a very basic way, and in relation only to its economic dimension, such as the export and import of goods and services, international capital mobility, labor mobility, and technical knowledge across national borders (Freeman 2018).

This new global context helped that many companies decided to relocate (offshoring) and outsource (outsourcing) many activities to third countries. Nowadays, manufacture process and services can be “sliced” in production units, each corresponding to a different task. These production units are relocated to those places where the work can be done most efficiently, often in a third country (Inomata 2017). The efficiency gains obtained from lower cost of production factors, particularly labor, the access to raw materials, or more favorable taxation systems, among others, were proportionally higher than the rise in transaction costs associated with logistics and communications.

Within this context, the manufacture of goods and the provision of services were no longer always produced in the same company, or in the same country, but can involve many companies, in different countries. It can even involve the same company, in different countries, that is, a multinational enterprise (MNE). (An international company is that one with export and import operations. A Multinational Enterprise (MNE) is one that has investments in two or more countries. All multinational companies are international; however not all international companies are multinational.) Thus, Global Value Chains emerged (GVCs), in which the relevant issue is not only the firm competitiveness, as the value chain theory aims, or the movement of final products, as classical international trade theories have analyzed, but also the cross-national transfer of tasks, focusing on the value added or generated by these tasks (Inomata 2017).

As multinational companies increased, and global value chains became longer and more complex (greater number of activities, increasingly specialized and carried out in different locations and countries), world economies were more

integrated and more interdependent. This makes more difficult to conceive national industries as self-contained systems and national economic performance as endogenous (Sturgeon and Memedović 2011). Since the 1990s, global value chains became one of the main drivers of economic development and structural changes at all levels of economic activity: companies, industries, countries, regions, and the global economy (Sturgeon and Memedović 2011). In recent years, events such as the 2008 financial crisis or the Covid-19 pandemic, a new industrial revolution based on information technologies and social and cultural changes that demand a more sustainable economy have generated changes and new trends in the configuration of GVCs. These new trends are generating structural changes in international trade and national economies in which firms play again a crucial role.

GVCs and their role in the economic performance of countries, industries and firms have been extensively discussed in the management and economics literature. The present work does not aim to perform a detailed review about GVCs literature. Instead, we try to facilitate a comprehensive understanding of the concept of GVCs. We first discuss the origin and evolution of the concept, by explaining key concepts and different conceptualizations of the term. Secondly, we summarize the main GVC analytical approaches. Finally, we discuss the recent changes and future perspectives generated by the rise of the sustainable economy and the arrival of the industrial revolution 4.0.

What Is a Global Value Chain? Origin and Conceptualization

The concept of value chain arose within the field of strategic management, as a tool to increase the efficiency and competitiveness of companies through the organization of transactions that take places during the production process. Over time, as companies began to organize production activities in different locations and outsource part of its production to third companies, the concept of value chain began to coincide and interact with

another relevant concept for business management such as supply chains, to that time mainly related to logistics. The parallelism between value and supply chains began to be even greater when, in line with the fall in trade barriers and advances in communication and transport technologies, companies started to relocate part of their activities beyond their national markets (offshoring), and in many cases, outsource tasks and services in third countries (outsourcing). It is at this time where value chains take a leading role in the development and understanding of international trade and national and regional economies, until they become a key element of global economic development and of countries.

Despite the relevance of GVCs, and the studies that have conceptualized the term and developed methodologies for its analysis, there is not always a consensus on its definition and use. The large number of economic activities and areas of knowledge in which they are relevant, as well as the different approaches to their study, for companies, industries, countries, and international trade, means that the definition and use of the term is not always clear and that it is even used as a synonym or replaced by other related concepts. In addition, the concept of GVC is in continuous development, and it evolves hand in hand with changes in the environment. Then, firstly, we try to present in a simple and clear way what a GVC is and its relation with other relevant terms.

Michael Porter first defined the concept of value chain as a set of activities that a firm performs to deliver a valuable product or service to the market (Porter 1985). The value added in the product is the result of the aggregation of the value added in each of different activities. In order to be competitive, the company must analyze how efficient it is in performing each of these tasks and outsource to the market or relocate to another location those in which it is not able to be efficient enough. The efficiency of each activity determines cost and margins, that is, firm's profitability. So, this model has been a key strategic management tool to understand the value creation process in organizations, and improve their competitiveness. According to Porter, a value chain can be broken into five primary activities: inbound

logistics, operations, outbound logistics, marketing and sales, and service. Porter's definition also considers four secondary activities that support primary activities in one or more of the primary ones: procurement, human resource management, infrastructure, and technological development.

The concept of value chain can be divided in two. On the one hand, a simple value chain describes the full range of activities required to bring a product or service from conception, through the different phases of production, and delivery to final consumers. On the other hand, in order to describe a more complex reality, the extended value chains consider also more activities and agents involved in the development of the product or service. Even, in the reality, the configuration of a value chain can be interconnected and interrelated with other value chain. Thus, in many occasions the definition of a value chain includes activities that are part of other value chains (Kaplinsky and Morris 2000).

A previous concept related to value chain is the supply chain. Originally, the supply chain had a conception more oriented to operations management and to logistics. The supply chain was defined as the set of operations and processes necessary to produce and deliver a product to the consumer. Later, with the globalization of production chains, production processes became more integrated and interrelated, and while their efficiency increased, so did the complexity of their management. As a result, supply chain management went beyond logistics, increasingly incorporating other business and management functions within and between companies (Jones et al. 2019). According to Lariviere (2018), supply chains are all the resource and processes required to fulfill the demand for products, both the physical ones and nonphysical assets. In the same line, Chopra and Meindl (2010) indicated that a supply chain consists of all agents (manufacturers, suppliers, transporters, warehouses, retailers, and customers) and, within each organization, all the functions involved, directly or indirectly, in fulfilling a customer request. This last definition, to a certain extent, reflects the two conceptions – that of the original value chain in the internal

dimension of the company and that of the supply chain, more oriented toward the logistics that takes place between the different stages of the production of a good or service.

In summary, a supply chain is the set of logistics activities, physical and nonphysical resources used to manufacture and make a product or service available to the consumer, that is, it has a more operational focus. On the other hand, the value chain represents the set of activities necessary to manufacture a good or service, each of which generates added value to the product, which represents a more strategic management approach.

The concept of GVCs or global supply chains (GSCs) is the international extension of these definitions (Jones et al. 2019), simply due to the fact that the activities that occur in these chains have been developed in different countries. The production is divided not only within a factory or a single firm but also in production and commercial chains that link multiple firms, facilities, infrastructures, and companies located in different countries, which conform a value adding chain of activities (Sturgeon and Memedović 2011). That is why many authors consider GVCs as the evolution to an international dimension of Porter's value chain concept, in a new context such as that of a globalized economy. These authors define the GVC as the set of activities that it is necessary to develop to obtain a good or service, and that take place in two or more countries. This is the case of Nguyen et al. (2021) who consider the global value chain as a "globalized production line in which many countries participate in various stages including concept, manufacturing, and logistics."

However, there are authors who defend that the GVC is not an extension of Porter's value chain, but something else. Inomata (2017) considers that different from a GVC based on Porter's value chain concept focused in how value distribution structure affects the internal firm's configuration, the main objective of GVC studies is to explore the interplay between value distribution mechanisms and organization of the cross-border production–consumption nexus. This is a conceptualization more based in the definitions provided by Global Value Chains Initiative (2000–2005), later improved by Gereffi et al. (2005). These

authors provided definitions focused on the governance structure of organizing international production networks, with an international trade approach. According to these authors GVC studies have to pay attention to the forms of transactions between stakeholders since the way transactions take place reflects power relations between the parties, which ultimately determine value distributions along the value chain.

In reality, in most cases, the use of some definitions or others depends on the approach from which they are made, that is, what is being analyzed, and from what dimension of knowledge. It is not equally understood what a GVC is when studying the organization of activities in a firm, than when considering the implications for international trade. In order to further clarify this issue, the next section briefly overviews the main approaches when studying the phenomenon of global value chains.

Global Value Chain Analytical Approaches

To discuss the different approaches with which GVCs are analyzed, we draw on the review work carried out by Jones et al. (2019), who in a simple and very didactic way grouped the GVC analytical approaches into four major categories (Table 1), of which we discuss the two of them more related to firm's management, the supply management and the industry/product approaches.

Supply Chain Management

One of the main contexts in which GVCs are considered is related with supply chain management (SCM) from the firm's perspective. SCM is a business analytical framework used by companies to improve firm competitiveness in the context of global manufacture processes (Jones et al. 2019). The development of the SCM coincides in time with the appearance of the value chain concept, and with the internationalization of the activity of companies, time at which the study of logistics and operational activities evolves toward a more multidisciplinary and integrative management dimension.

Global Value Chains, Table 1 Major global value chain (GVC) analytical approaches

Analytical approach	Description
Supply chain management	A business analytical framework from the firm's perspective on how a firm can enhance competitiveness in the context of GVCs
Industry or product case studies	In-depth GVC analysis from the industry's perspective, such as value distribution along a supply chain, key play
Input-output based analytical approaches	Quantitative analysis from a macro perspective, by applying the input-output framework to measure a country's specialization in global production networks and its GVC participation
Other analytical approaches	Applications of general and partial equilibrium models, as well as gravity models, for GVC-related analysis

Source: Jones et al. (2019)

The vision of the SCM has evolved since its conception as a tool for coordinating the tangible functions of the activity, manufacture, and logistics (Lee and Billington 1992) along the entire value chain, from raw material to the end user (New and Payne 1995), both in the internal tasks and relationships within the organization, and external ones with suppliers and customers throughout the supply chain. At present, it is more identified with a cross-functional function that applies an integrated business approach for maximizing value creation and achieving sustainable competitive advantages (Jones et al. 2019). This new vision does not consider the supply chain as just another function of the business activity but as a strategic function that integrates all the tangible and intangible aspects that interact in it, from logistics and production, to the necessary management and information systems (Park et al. 2013; Stadler 2015).

Industry or Product Case Studies

The structure that a value chain adopts and the interactions and relationships that occur between its agents condition and determine the

competitiveness and success not only of companies but also of products and industries as a whole. On the other hand, policy makers demand information in order to implement governance actions and develop policies that favor the competitiveness of their companies and the economic development and well-being in their territories. Furthermore, society and consumers increasingly demand greater transparency in the operation of GVCs, in order to know where and how the goods and services they consume are produced, as well as the way in which value creation is distributed throughout.

There is a great variety of analyses, from those works that are limited to identifying the steps in the value chain, the involved agents and the direction of the flows between them, to the works that manage to determine the competitive relationships between the agents and the added value that is generated at each stage. The scope of the works is conditioned by the availability of information, and in the case of GVC, obtaining information is even more costly and complicated. As a general rule, the more information a methodology provides, the greater the amount of information that is needed, and therefore, its application is more difficult and involves a greater consumption of resources, both in time and money. The studies that best characterize the global value chain are usually static, due to the enormous consumption of resources involved in carrying them out or the inability to obtain the information.

Future Directions: Toward a More Sustainable GVCs

The effects of GVCs depend on the particular case conditioned by multiple factors such as the production stage, location, product, or regulations among others (Jones et al. 2019). GVCs condition the competitiveness and economic development of companies and countries, and the participation in them generates opportunities, not only in terms of increasing international trade but also in accessing resources, technologies, and knowledge and developing efficiency and productivity gains. In the case of employment, in developed countries

there is no consensus on the impact of GVCs on total employment (Jones et al. 2019), but in developing countries, participation in GVCs generates a prior positive impact on employment, since demand for skilled labor increase, local workers receive trainings; and then, workers also move from MNEs to local firms, bringing acquired skills and knowledge with them (Taglioni and Winkler 2016). However, in some cases development is not sustained over time, redundancy of low-skilled labor occurs, and countries end up immersed in the middle-income trap. (A country in the middle-income trap is the one that has lost its competitive advantage in the export of manufactured products because of the rise in wages due to the economic development experienced. However, it does not have the capacity to match the more developed economies and the high value-added markets.)

In the last 10 years, GVCs have undergone profound changes according with several economic, political, technological and social structural changes. Since the financial crisis of 2008, the economic recovery has reduced the GVCs production length (the number of activities or stages during the production process), and more and more tasks, although may continue to be offshored or outsourced, are carried out in the same country. Furthermore, recent events have evidenced the fragility of GVCs, due to the failure of one of its stages, as in the case of Suez Canal obstruction in 2021, and the risks to citizens' health and safety, such as in the case of the COVID-19 crisis. Below we summarize some of the main drivers behind the transformation of GVCs in the coming years.

Nowadays, there is a political and social trend in favor of a Green economy, more socially and environmentally sustainable, and firms are gradually incorporating sustainability criteria in their production processes and in their organizations. Thus, methodologies such as the Life Cycle Assessment (LCA) or the Social Life Cycle Assessment (S-LCA) emerge to facilitate organizations to evaluate and incorporate into their management the criteria and priorities included in the Sustainable Development Goals (SDGs), in the context of the 2030 Agenda for Sustainable

Development. These new methodologies are based on a value chain vision, in which the different stages in the production processes are analyzed, considering how the different activities, whether direct or indirect, generate social and environmental externalities. In the case of multinational companies, the GVC approach is essential to be able to make an adequate evaluation of these externalities.

Many companies and products are efficient from an economic point of view, but they are not environmentally and socially sustainable. This gives rise to the emergence of reshoring, that is, the return of the production activities to the countries of origin. Reshoring minimizes or eliminates outsourcing costs (Nguyen et al. 2021) and enhances internal collaboration across firms' departments (Wan et al. 2019). On the other hand, the return of activities facilitates in many cases a more environmentally sustainable production, and positive social impacts, increasing employment, wealth, and taxes. In most cases, governments of developed countries favor reshoring by reforming tax policies, removing business barriers, and increasing domestic manufacturing capacity. On the other hand, developing countries that carry out these tasks see their participation in GVCs at risk (Rasel et al. 2020).

These changes take place thanks to the fact that the industrial revolution 4.0 is taking place in parallel. The global economy is gradually transforming from an economy based on manufacturing to a digital economy based on technological advances, information, and data, characterized by a fusion of technologies between physical, digital, and biological spheres (Nguyen et al. 2021). This process has given rise to the so-called Globalization 4.0 (Schwab 2018) in which social and environmental criteria take a greater relevance (Bridge 2002) and production is less dependent on labor, since many tasks performed by workers are replaced by technology.

The combination of a globalization that adopts the postulates of a green economy and the environmental and social objectives of the 2030 agenda with the industrial revolution 4.0 create a new paradigm for firms and country development and sustainability. There are opportunities for

development thanks to a new positioning in the development of global value chains based on new technologies. However, there is a risk that this new globalization will worsen the situation in countries that have already fallen into the middle-income trap. The role of international organizations and governments in matters of governance will be essential to enable companies to be competitive and sustainable in this new era.

Summary

Many authors consider GVCs as the evolution to an international dimension of Porter's value chain concept, in a new context such as that of a globalized economy. GVC analytical approaches can be grouped into four categories: supply chain management, industry or product case studies, input-output based analytical approaches, and other analytical approaches. The effects of GVCs depend on the particular case conditioned by multiple factors such as production stage, location, product, or regulation. The global economy is gradually transforming into the so-called Globalization 4.0 in which social and environmental criteria take greater relevance, so there are opportunities for development to enable companies to be competitive and sustainable in this new era.

Climate change disasters; Climate warming;
Greenhouse effect; Increasing climate change

Definition

Before defining the concept of global warming, the concept of the greenhouse effect must be explained to better understand this definition. The greenhouse effect can be explained as the following:

One part of the oscillated radiation from the sun is directly reflected into space by the atmosphere; others are absorbed by the earth. A significant segment of the long-wave radiation emitted from the heated earth is absorbed by the atmosphere and is reflected to the earth, and one part is sent directly into space (Dinçer et al. 2010). As the gases in the atmosphere are more permeable to short-wave rays coming from the sun and less permeable to long-wave radiation emitted from the earth due to the accumulated greenhouse gases, the parts close to the ground become warmer than expected. This is called the greenhouse effect (see Fig. 1).

The natural greenhouse effect, in fact, is not caused by the problem of global warming. Significant increases in greenhouse gas emissions have occurred during the short period since the Industrial Revolution (Dinçer et al. 2013). Greenhouse

gases, which have long life and have been in the atmosphere for decades, accumulate in the atmosphere. This increased greenhouse gas concentration, like a blanket, captures the long-wave rays emitted from the earth and reflects them back to the world. This cumulative greenhouse effect causes the earth's surface to warm up more than it should naturally. In other words, depending on the rapid increase in the accumulation of greenhouse gases released into the atmosphere, the increase in temperature observed on the earth and in the lower parts of the atmosphere as a result of the strengthening of the natural greenhouse effect is called global warming.

Increasing the concentration of greenhouse gases in the atmosphere leads to the strengthening of the natural greenhouse effect, which allows living things to live at a temperature by providing energy balance (Türkeş 2001). The augmented greenhouse effect disrupts the world's energy balance and causes the earth to warm up more than expected. In this respect, the average surface temperature has increased by about 0.9 °C from the beginning of the twentieth century to nowadays (IPCC Climate Change 2013; Djalante 2019). While the increase in the average surface temperature, which is called global warming, causes climate change, on the one hand, the global warming process continues to increase due to the changing climate (Eco Securities 2006). Furthermore, several climatic feedback mechanisms, driven by external forces, such as solar activities, volcanic activities, and changes in the Earth's orbit, raise violence in the heating process. Global warming steps are shown in Fig. 2.

Greenhouse Gases Effective in Global Warming

Rays returning to space, especially infrared charged rays in sunbeams which reflected into the atmosphere from the sun to the earth, is prevented by greenhouse gases. Therefore, global warming occurs, and as the number of greenhouse gases in the atmosphere increases, the greenhouse effect augments.

The main types of greenhouse gases in the atmosphere are water vapor (H₂O), carbon

Global Warming, Fig. 1 The greenhouse effect (Cesur 2014)

Global Warming, Fig. 2 Global warming process

dioxide (CO₂), methane (CH₄), nitrous oxide (N₂O), perfluorocarbons (PFCs), hydrofluorocarbons (HFCs), and sulfur hexafluoride (SF₆).

Carbon dioxide (CO₂): Carbon dioxide is the most common type of greenhouse gas in the atmosphere and contributes the most to global warming. Its ratio in greenhouse gases is 82%. Because, carbon dioxide transmits on a large scale to the short-wave rays directly from the sun, while retaining long-wave rays emitted from the earth. It has been found that CO₂, which has not changed in the atmosphere for

millions of years, has increased by 31% since the beginning of the Industrial Revolution. While the annual increase of CO₂ in the atmosphere in the 20 years before 1990 was 0.4%, the increase in the following years ranged from 0.2% to 0.8% (Earth System Research Laboratory). Most of the CO₂ released into the atmosphere due to human activity is caused by the fossil fuels used extensively. 80% of the greenhouse gas effect produced by developed countries in the world and 60% of the total greenhouse gas effect globally is composed of carbon dioxide.

Methane (CH₄): It has the most greenhouse effect after CO₂ in the atmosphere. The amount has increased by 151% since the beginning of the Industrial Revolution and continues to raise. Nearly half of the current methane gas emissions result from the use of fossil fuels, the burial of waste and residues, human activity, such as animal husbandry and rice farming.

Nitrous oxide (N₂O): It has raised by 17% since the Industrial Revolution. Approximately one-third of the nitrous oxide released into the atmosphere accrues during the use of soils open to agriculture, the chemical industry and the production of cattle fodder. The amount of N₂O in the atmosphere is gradually increasing.

Halocarbons: Halocarbon gases such as chlorofluorocarbons (CFCs) are released using sprays in the perfume industry and coolers into the atmosphere. These gases by convert O₃ in the ozone layer of the atmosphere to oxygen and its derivatives cause the ozone layer to become thin. Thus, because of the ozone layer which holds a large part of the ultraviolet rays coming from the sun is thinner, more than ultraviolet rays come to the world and cause various damages and warming on the earth. Halocarbon gases are also gases that cause global warming by holding the sun's rays reflected the atmosphere.

Ozone (O₃): The ozone layer in the atmosphere both plays a very important role in making the world a habitable planet by absorbing excess ultraviolet rays from the sun, and it also provides a living environment for living things by staying at certain degrees of the earth's temperature by being a greenhouse effect gas.

Carbon monoxide (CO): It is very dangerous having too much in the atmosphere since toxic gas. CO, which also has a greenhouse effect in the atmosphere, is mostly released to the atmosphere as a result of human activity. More CO is emitted from fossil fuels that are not burned well and their level in the atmosphere is increasing.

The ratio of greenhouse gases in the atmosphere is quite low (less than 0.1%). To maintain the balance of climate systems on earth, although they are present in low levels in the atmosphere, it is very important to maintain the levels of greenhouse gases in the atmosphere at the previous

level. The average temperature of the earth is about 15 °C. If the greenhouse gases were not in the atmosphere, the Earth's temperature would be much lower than it is now, so there would be no chance of living being in the world. When the ratio of greenhouse gases in the atmosphere increases, as a result of global warming, the icebergs in the poles and high mountains will begin to melt, and there will be no possibility for plants and animals to survive because of forest fires due to extreme heat. As the seas get warmer, the melted CO₂ will be given to the atmosphere and the greenhouse effect will continue to incrementally.

Greenhouse gases causing global warming; mostly due to combustion of fossil fuels (energy generation, heating etc.), industry (energy-related and energy-exterior such as cement production with chemical processes), transport, land use change, waste management, and agricultural activities (energy-related and energy-exterior such as stubble burning, paddy production, livestock breeding and fertilizer use). Table 1 shows the types of greenhouse gas emissions from some industrial activities. Table 2 presents the relative impact of greenhouse gases and annual growth rates (Alper and Anbar 2007).

Greenhouse gases have a very long life and the concentration of greenhouse gases in the atmosphere is determined by the emissions of greenhouse gases 300 years ago or earlier. Therefore, the global emission level should be less than the present consideration for maintaining atmospheric greenhouse gas concentrations at a certain level. Although specific targets are not defined, the goal of keeping the carbon dioxide volume in the atmosphere at 550 ppm is a widely used measure. On the other hand, most scientists state that even this level may be too high to prevent significant climate change impacts (Henderson et al. 2018; Nicholas 2007). The Intergovernmental Panel on Climate Change (IPCC) estimates that there is a 60% reduction in global greenhouse gas emissions to achieve this goal (Rogelj et al. 2012). But, developed countries will need to reduce their greenhouse gas emissions to higher rates (such as 80–90%) for allowing less developed countries to complete their economic growth and progress.

Global Warming, Table 1 Greenhouse gas emissions resulting from industrial production

Greenhouse gases emissions	CO ₂	CH ₄	PFC/HFC	N ₂ O	SF ₆
Aluminum production	✓	✓	✓		✓
Other metals production such as magnesium	✓	✓			✓
Manufacture of Iron-steel and alloy that including iron	✓	✓			
Nitric and adipic acid production	✓			✓	
Ammonia production	✓				
Urea, fertilizer and petrochemical production	✓			✓	
Other materials production adding on cement, lime and mortar	✓				
Petroleum and gas production	✓	✓			
Electricity generation	✓	✓		✓	
Coal mine	✓	✓

Pulp production	✓	✓			
Wood/charcoal production	✓	✓			
Halocarbons and SF ₆ production			✓		✓
Agricultural crop production such as palm oil	✓	✓			
Sugar and alcohol factories	✓	✓			
Waste/trash management	✓	✓			

Global Warming, Table 2 Relative and annual increase rates of greenhouse gases

Greenhouse gases	PFC/HFC	CH ₄	O ₃	N ₂ O	CO ₂
Relative effect (%)	15–25	12–20	8	5	50–60
Annual rise rate (%)	4–5	1	0.5	0.2	0.3–0.5

Whereas, this is very difficult to achieve in an environment where world energy demand is increasing. The International Energy Agency estimates that world energy demand in 2030 will be 50% higher than in 2005 (United Nation Climate Change Agency 2018; Sullivan 2006).

Effects of Global Warming

The world climate system has sometimes entered a period of heating or cooling ever since thousands or even millions of years and has undergone conditions that we might call abnormal (Khan 2019; Kweku et al. 2017). Separately the known Glacial and Interglacial periods, disasters have occurred as a result of volcanic activities and their results have been reflected in climate changes that lasted for months, hundreds and even thousands of years. Especially in the last 30 years, very different from the previous climate changes, causing many natural

disasters which trigger cumulative and influencing each other, occurrence event chains with global warming phenomenon raised (Peters et al. 2013). It is mentioned that the problems will continue due to the increasing global warming and that the future of human beings and other living beings will be in danger as a result of catastrophic irreversible disasters.

Some events caused by global warming are as follows:

Glaciers in the arctic and high mountains continue to melt due to increased global warming. Sea level has raised by 15–20 cm in the last 20 years.

The ozone layer absorbs most of the ultraviolet rays from the sun and protects living things from the harmful effects of these rays. Halocarbon gases, such as CFCs, which cause the atmosphere's ozone depletion, increases global warming due to more greenhouse effects.

Depending on global warming that causes climate changes,

Natural disasters such as flood, landslide, and erosion have increased. Slowly falling rain takes most CO₂ gas, even the SO₂, and H₂S gases into the body, and falls to the ground. Meanwhile, the greenhouse and polluted gases in the atmosphere are cleaned. But rapid and excessive rainfall contributes little to the reduction of greenhouse gases in the atmosphere.

While the heating of the earth and the atmosphere warms the seas and oceans, reducing the number of species here, it increases the effects of global warming by releasing the dissolved CO₂ into the atmosphere.

Global warming will reduce the capacity and reserves of watersheds and enhance environmental pollution as a result of increasing need. Water is mandatory for life, and human social and physical life is closely correlated to the use of water.

Desertification will become widespread in the world because of excessive temperature rise.

Increased forest fires will spread epidemic diseases here with aridification of the climate.

Extremely hot and cold will increase mutations in chromosome number and structure of living organisms and will lead to a change in the hereditary structures of living things.

Frozen soils in the Polar Regions will be thawed as a result of global warming and will release the greenhouse gases in their bodies for thousands of years.

Global warming will gradually reduce the temperature difference day and night.

Atmospheric disasters such as tornadoes and lightning will increase.

Global warming will trigger the chain of acid rains and many natural disasters.

Overheating will reduce the water capacity of lakes and rivers.

Sudden climate changes as a result of global warming will increase the disease by making it difficult for the body to achieve homeostasis.

All these negative events will incline a depression of morale, which will lead to sensitization of the mental structure and increase of disputes.

Human Role and Effects in Global Warming

The rapid mechanization process after the Industrial Revolution, changes in the production and consumption structure, population growth, and urbanization brought forth the intense need for energy. Especially after the Second World War, the economic growth demands of the countries brought about an increase in energy demand. This energy need is mostly met from fossil fuels such as coal, petroleum, and their derivatives, causing the destruction of the environment and changing the composition of the atmosphere. In this process, the concentration of carbon dioxide, which is one of the greenhouse gases, caused by the use of fossil fuel, has increased gradually in the atmosphere. The CO₂ concentration, which was almost constant at 280 ppm in the pre-industrial revolution period, exceeded 400 ppm as of 2014. In 2018, it reached an average of 408.52 ppm. Moreover, as a result of deforestation, agricultural activities, wrong land use, and industrial processes, other greenhouse gases such as methane, nitrous oxide, and fluorinated gases increased in the atmosphere during this period.

The main reason for global warming is that the concentration of greenhouse gases in the atmosphere is much higher than the required values. Therefore, the main source of greenhouse gas emissions is the rapidly increasing economic activities with the Industrial Revolution. This is seen from the rise in the number of greenhouse gases in the atmosphere since the Industrial Revolution.

Global climate modeling related to global warming predicts an increase in average surface temperatures between 1.4 °C and 5.8 °C between 1990 and 2100. In the 5th evaluation report of the intergovernmental panel on climate change (IPCC) published in 2013, it is stated that global warming on the climate system is an indisputable and human influence in this warming is clearly present. The following determinations are referred.

Warming in the global climate is certain and the lasts for 30 years, the hottest year passing through the sequential 30 years since 1850, the

hottest 10 years of the twenty-first century. The total heating between 1850–1900 and 2003–2012, calculated based on the longest single data set available, is 0.78 °C. The expected increase in global temperatures will probably be between 1.5 °C and 4.5 °C. Global average surface temperature data in the 1901–2012 period during the longest period in which regional trends could be adequately calculated showed a linear increase of 0.89 °C. The atmospheric concentration of carbon dioxide (CO₂), methane (CH₄), and nitrous oxide (N₂O) increased more than ever in 800,000 yearly periods. CO₂ densities increased by 40% compared to the pre-industrial period. Paleoclimatological data probably indicates that the 1983–2012 period was the hottest 30-year period in the last 1400 years in the Northern Hemisphere. Greenland and Antarctic ice shields continue to shrink by losing mass. Furthermore, these ice shields continue to decrease in Arctic sea ice mass and spring snow cover in the Northern Hemisphere in the last 20 years. The sea level rise rate observed since the mid-nineteenth century is greater than the average rise rate in the previous 2000 years. The average global sea level increased by 19 cm between 1901 and 2010. It will continue to rise during the twenty-first century. On a global scale, high numbers of cold days and nights are probably decreased, and the number of hot days and nights increased. Except for one scenario, global warming will continue after 2100 based on all new IPCC scenarios. More than 90% of the energy accumulated in the oceans of the period 1971–2010 is linked to global ocean warming and will continue in the twenty-first century. The heat will pass from the surface to the deep ocean, affecting ocean circulation. According to the period 1986–2005, the change in the global average surface temperature during the 2016–2035 period is likely to be in the range of 0.3–0.7 °C.

Summary

Global warming, seen as one of the biggest environmental problems threatening our world, has most importantly emerged as a result of fossil

fuel use, industrialization, energy production, forest depletion, other human activities, and economic growth and population increased accelerated this process. In parallel with the rapid rise of carbon dioxide and other greenhouse gas levels in the atmosphere since the Industrial Revolution, a significant increase also in average temperatures has been observed.

Global warming will cause changes in the ecosystem. If the increase in global average temperatures exceeds 1.5–2.5 °C, the risk of depletion of approximately 20% to 30% of plant and animal species will raise. In the case of increased temperature of 1.5–2.5 °C and accompanied by the concentration of carbon dioxide in the atmosphere to this, significant changes in the structure and function of the ecosystem, ecological interactions of species, and geographical distribution of species are expected. Ecosystems are at risk; these are particularly glaciers, coral reefs and coral islands, northern forests and tropical forests, and poles and Alps.

Changes made by global warming in climatic conditions, environment, and ecosystem will also affect people's lives. For example, there will be migration from regions where the effects of global warming are intense to other regions. These migrations will bring along other problems. People will be able to accept lower salaries to work in regions with more favorable climate. In these regions, real estate prices and house rents will tend to increase. Depending on the effects of climate change, expenses of people may increase. Except for migrations, the increase in regional or inter-country differences may lead to an increase in unrest, fights, and conflicts. Terror incidents may increase, and regional or inter-country conflicts may arise in the sharing of water resources.

Outside of sectors such as agriculture, energy, and tourism, global warming will affect many other sectors directly or indirectly. The sectors most sensitive to emission reduction policies are energy-intensive sectors such as cement, aerospace, metal, and mining and the transportation sector and fossil fuel consuming products such as automobiles. Besides food, construction, insurance, and banking sectors will also be affected by global warming. Not only manufacturers but

consumers will be adversely affected by global warming. The most important risk for consumers owing to global warming will be price increases in food and energy products.

As a result, since global warming occurs as a result of human activities, the excessive and unconscious use of fossil fuels that causes this should be discontinued, and restriction should be introduced. On the other hand, depending on the rapid increase in world population, population growth should be kept within acceptable limits, because of efforts for the solution of these people's food, shelter, warming, and health problems which giving more emissions of greenhouse gases into the atmosphere that increasing air, soil, and water pollution. The human efforts that meet the energy needs from other sources instead of fossil fuels should be increased. Clean energy should be provided by making more use of sun, wind, sea current, sea wave, geothermal, and rivers. Unconscious use of consumables should be avoided in efforts to raise the level of life. Moreover, all precautions should be taken as soon as possible to ensure that natural events occur within their cycle.

[Glocalism](#); [Glocalization](#); [Grobalization](#); “[Think Global, Act Local](#)”

Definition

Glocality refers to the confluence in certain social activities between the local and the global. Specifically it has to do with the social groups (person, company, organization, or community) that “think globally and act locally.” The term glocality refers specifically to organizations or social groups adapting their goods and/or services to the different local environments where they operate, but without losing their characteristics and/or advantages that make them globally competitive. The glocality represents an important advance of the globalization phenomenon where

people and organizations can approach different situations with a perspective that gives them a better understanding of the situations that organizations face in their international operations (Tien and Talley 2012; Rao 2010).

Introduction

According to Roudometof (2018), it is impossible to discuss the global without touching the local. As the definition indicates, glocality is the mixture between the global and the local. It is a hybrid of two concepts that have different essences, these are globalization and localization. Glocality is also considered as a response to globalization through the reinforcement of the cultural identity of each society (Maynard 2003; Rao 2010). This concept has been used to explain the impact of globalization in different areas of society (Giuliannotti and Robertson 2012).

This combination of words exemplifies in its simplest way a product or service that is developed and distributed globally but is adapted with unique characteristics for a specific market (Shamsuddooha 2008). The first to mention the term glocality was Robertson (1992), this term is mainly related to sociology. It is important to understand how these two concepts are intertwined to reach glocality.

First, it is important to note that the term globalization is relatively new, it appeared in the 1960s but took relevance during the 1990s (Beyer 2007) but not the phenomenon itself. Globalization is a phenomenon that has existed for hundreds of years. Some authors (Friedman 2006) point out that this phenomenon began when Christopher Columbus landed in America at the end of the fifteenth century. Moreover, globalization is also considered to exist since primitive man from Eurasia crossed the Bering Strait and began to populate America (Tropea 2014). However, the first antecedent of the term globalization is proposed by Marshall McLuhan in the 1960s (Adam 2016) with his term “global village.” Later, one of the first to coin the term “globalization” as such was Theodore Levitt (1983) with his classic article “The Globalization of the Markets.” Although the boom of the term takes up much strength

during the 1990s due to the development of the Internet in the everyday life.

Second, localization is a broader term. In order to narrow the term we refer to the business-centric location. According to the foregoing we can understand that this term comprises several elements such as physical closeness with customers, competitors, and suppliers (Rydehell et al. 2018). In addition, a suitable location refers to important benefits for companies such as knowledge of customers and their environment, as well as development of business networks. Also a suitable location allows companies to have access to sources of innovation and development of new technologies.

In this vein, Dunning (1980) points the location as an advantage for the international expansion of companies. It states that within the benefits of localization not only the basic factors of production are found (land, labor, and capital), the local market structure, policies, and laws of the country's governments are also included. According to Villena (2000), the local has been grouped into four analysis units such as: state-national, regional, urban, and community-local.

However, the word "glocality" derives from the Japanese term "Dochakuka" which is the elaboration of global products, procedures, and services to be adapted to specific needs of a culture (Prakash and Singh 2011; Robertson and Giulianotti 2006; Salazar 2005). Given the above, glocality is understood as a way of acting on the business strategy. It seeks to develop strategies, products, and/or services of a global nature, but at the same time that they have the quality to be offered with specific characteristics for a market or group of markets with specific needs. The above with the aim of taking advantage of the benefits of globalization and localization together.

Key Issues

It is important to mention that there is no current glocality theory (Roudometof 2015). According to Robertson (1992) the interdependence of the universal and the particular is the essence of globalization. The above means that globalization makes many elements of everyday life common

in other parts of the world. For example, the use of credit cards, travel, and airports. But on the contrary also in every part of the world these common elements have their own characteristics.

Although glocality does not have its own identity as a theoretical reference, there are three main currents that have addressed the glocality. As noted above, the first to use the term glocality was Robertson (1992), who stated that glocality is included within globalization, that is, an integral part of the globalization phenomenon. The way this happens is that the global interprets the local in such a way that they manage to interact within each other.

The second current on the glocality is proposed by Ritzer (2003, 2004) in response to the contributions made by Robertson (Roudometof 2015). This current replaces the globalization as "grobalization" which is a phenomenon with imperialist ideas of the different international actors (for example, nations, firms, and organizations), which have as main objective to impose on others. Therefore, Ritzer (2003) asserts that globalization is used to promote the "grobalization" of culture. This current indicates that the local exists outside the global.

Finally there is a third current to address the glocality. This gives autonomy to the glocality, that is to say that it is a phenomenon different from the globalization and therefore it has to be approached from another perspective (Alexander 2003). The important thing is to understand the way in which the global and the local interact in modern societies (Roudometof 2015).

Afterward, it is inferred that the glocality is presented as an advance in the phenomenon of globalization, it allows to understand the connections between the global and the local (Salazar 2005). It is one of the ways in which globalization is currently implemented. It is important to mention that the difference between glocality and globalization is that the first is a way that has adopted globalization to increase its intensity and influence in societies. The awareness of companies of the importance of the specific needs of consumers worldwide has triggered an increase in globalization in the markets.

How to exemplify the interaction between the global and the local? A classic example is using

the multinationals, natural agents of the glocality. In a country other than that of origin, multinationals can carry out two strategies. The first is a globalized strategy which refers to the development of strategies considering the world as a single market. Applying this strategy standardizes products and processes in the world. The second, localization strategy refers to applying specific tactics for a particular market, for example, car brands sell some models in some markets and in others not (Prakash and Singh 2011).

Another example of glocality is what happens with Indian films showed in India. In order to be more attractive to the local audience these films present characteristics of Hindu culture such as costumes and music. Despite the foregoing these films include global elements such as Westernized costumes, locations in different parts of the world (Rao 2010). The previous examples allow to visualize and understand the interaction between the global and the local as strategy in companies and in industries.

The use of the globalized strategy and the localized strategy in a joint manner is a sample of glocality. It is important to mention that glocality not only applies in the field of business, but it also applies in different knowledge bodies such as sociology, geography, and marketing. This is important because it is possible to be approached from different perspectives.

However, it is important to mention that glocality is not a new phenomenon, it has existed since globalization emerged. It was discovered due to the vertiginous progress of globalization. This breakthrough generated new ways of being able to interact with the various social actors to strengthen the globalized movement, in whether the glocality is a refined and focused form of globalization (Khondker 2005).

In addition, glocality allows to use the best of both worlds. Specifically the benefits of localization such as the environment, consumer characteristics, and access to the region's own resources, as well as the benefits of globalization such as competitiveness, product diversity, and access to information. This somehow increases the success of companies in global markets.

According to the above, what are the key areas of the glocality phenomenon? The first refers to the place of glocality within globalization, if it is within the same phenomenon, whether it can be considered separately or if it is a breakthrough in the globalized world (Alexander 2003; Ritzer 2003; Robertson 1992). Depending on where it is, it can be better analyzed. The second refers to understanding the impact that glocality has had in the various social and economic fields. This impact generates several questions about the effectiveness of this phenomenon for the different societies of the world.

Future Directions

Some research areas relevant to literature are identified. One of them refers to reducing the shortcomings of globalization, such as: inequalities in economic development, social exclusions, and loss of sovereignty (Bretos and Marcuello 2017). These shortcomings have represented important challenges for all social actors because they have generated problems to improve the transfer of benefits and equal development. It is also important to analyze the depth, that is, the degree to which it is possible: "Glocalize" without losing the essence of what it is and power in this way increases its benefits. The third challenge focuses on explaining the breadth of the glocality, this is about how far it covers, whether it covers only one sector, a society, an industry, or has already expanded in all areas.

Finally it is important to empirically test the glocality. It is important to analyze specific cases of companies that have glocalized their operations in order to understand what specific strategies they use. It is also appropriate to understand the differences in these strategies according to their country of origin and the international markets where they apply them.

Summary

Glocality, since the social point of view, is the point where local and global converge. In a

practical approach the term is associated to the adaptation and standardization of goods and services for different markets. Some scholars have asserted that glocality is not only a new kind of globalization, but is an advance of this. The glocality in the literature is represented for three main body of knowledge: first, glocality is an integral part of the globalization; second, it states that the local exists outside of the global; and third, glocality is a new phenomenon that is not related to globalization.

It is important to point out that glocality is not exclusive for business and management decisions, also it is useful to explain phenomenon for other social sciences. The essence of glocality is adapt the global to the local preferences without losing its global essence. On this regard it is important to understand the degree to which it is possible to adapt, not all the products and services have the same degree of adaptation. Furthermore, it is essential to understand the role that plays glocality in globalization phenomenon, in the way that we can understand this, we can do a better use of this as strategy.

Definition

Good governance is a challenging process resulting from a symbiosis between the mission of organization and the laws governing the smooth running of its activity, and also it is based on a series of quantitative assessments of reporting practices, indices, and reports that link performance governance that could contribute to the development of a performance improvement strategy. Finally, good governance is a complex concept with profound implications in the approach of an organization regarding social responsibility and business ethics, in full agreement with ensuring its legal responsibilities.

Introduction

The financial scandals that started in the second part of the twentieth century led to the need to develop

financial-accounting and managerial tools that would lead to the prevention and elimination of frauds and abuses. Financial scandals related to Enron, Exxon Valdez, WorldCom, and other multinational companies have shown that an inefficient allocation of short-term financial resources will have systemic consequences for long-term investments. Thus, an action was taken to reform the structure of organizations and capital markets by adopting stock market regulations and rethinking the duties and responsibilities of managers of large companies.

From the point of view of Anglo-American literature, good governance ensures that decisions are made and implemented in order to increase the well-being of the owners, which leads to actions that compensate for the need to protect shareholder risk and managers' responsibilities, by encouraging managers to take risks in order to increase shareholder income, but, on the other hand, managers must respond to the interests and other stakeholders, including the interests of employees. Holmstrom and Kaplan (2003) consider that it was exaggerated to present the negative results of US corporate governance failures, because, in the long run, US stock returns continue to outperform those of almost all other economies, suggesting that systemic losses are not too serious.

In a good governance process, organizations intertwine their strategies with the motivational elements of the stakeholders and analyze the role of their shareholders and of the boards of directors in promoting their own interests. Good governance offers a chance for both regulators and regulations to play a role in regulating employment in a way that serves all stakeholders in the best way possible. For example, regulatory authorities want to correlate social values with economic incentives and also to discourage corruption. On the other hand, stakeholders influence companies to react effectively to their values, and thus develop internal regulation to respond to challenges in the most effective way.

The complex concept of good governance implies stakeholder involvement in decision making, and the use of appropriate tools rather than governance programs leads to problem solving in a network system and decentralized power (Burlea-Schiopoiu et al. 2014).

Good governance aims to promote ways to comply with regulations and to put into practice responsible regulation that will synthesize some contradictory theories. As a result, medium- and long-term strategies need to be ordered in a pyramid-like hierarchy that encompasses more cooperative strategies that will prevent organizational failure.

Key Issues

The Features of Good Governance

The role of good governance is to prevent conflicts of interest and to protect the interests of investors through a set of rules and functional relationships that are established, on the one hand, between the management of the organization and the board of directors, and, on the other hand, between the shareholders and other stakeholders (Burlea-Schiopoiu and Popa 2013). Therefore, good governance contributes to a more efficient use of financial, human, and material resources, which leads to increasing investor confidence and other stakeholders in the management of the organization and, implicitly, to increasing the organization's reputation.

A number of elements are defining for good governance to provide the opportunity for both regulators and regulations to serve all stakeholders in the best possible way:

- Assessing the need for implementation of an organizational reform addressing issues of governance
- Analyzing how the implementation of a new set of governance rules will affect the interests of stakeholders
- Identifying key elements that influence the relationship between governance and the ethical principles of the organization
- Analyzing how the implementation of good governance system will increase the efficiency of organization.

A good governance involves a clear understanding of the roles of key actors involved in this process, such as board of directors,

management, shareholders, and relations between key actors and other stakeholders.

Organizations' failures and certain unethical managerial behaviors highlight the need for organizations to pay more attention to governance practices. The need to raise equity can have a positive impact on governance, especially if managers have to borrow to finance the acquisition of shares and then are forced to increase performance in order to repay the loans.

It should not be overlooked that the state needs to create an adequate regulatory environment to ensure that newly established relationships between newly privatized companies, financial and nonfinancial stakeholders, and lending institutions will focus on increasing economic efficiency and will promote organizational restructuring and technological modernization. In the underdeveloped market systems from the important transition economies, there are also measures that increase the entrepreneurial competences together with the development of the systems of good governance.

Monitoring, incentives, and other types of governance mechanisms are conceptualized and operationalized as independent, each having its own unique ability to influence the organization's strategies and performance (Cucari 2019). Thus, governance practices should be analyzed in interconnection and complementarity with the potential costs of the governance process.

The Impact of Principles on Good Governance

The divergence that is between the corporate governance systems depending on the institutional, legal, and cultural context of the organizations generated the idea that a sound good governance practices requires an effective exercise of ownership rights, setting standards transparency and fiduciary responsibility of the board of directors, establishing a remuneration policy for managers and for the members of the board, clauses regarding the disclosure of transactions with affiliated parties, a stronger protection of minority shareholders and an increased potential for shareholders to control the boards of directors, administration and participate in decision making.

Many international organisms and organizations elaborated principles of good governance.

Thus, the Council of Europe elaborated the Strategy on Innovation and Good Governance at local level, in 2008, and in this strategy are mentioned 12 principles. These principles play an important role in guidance of organization in issues related to accountability, legitimacy, efficiency and effectiveness, fairness and transparency, quality control, rule of law and regulatory framework, ethics, and financial management.

The organizations recognize the importance of principles in a good governance process, because using the principles the stakeholders cooperate in order to improve both the efficiency and reputation of their organization.

The respect and the putting into practice of the principles of good governance have a strong impact on the decision-making processes and transform governance into a strategic instrument that foster sustainability (Edgar et al. 2006).

Future Directions

In the future, a new approach to governance will be needed to effectively increase organizational standards and reduce corruption, because the good governance process comes from a conceptual context that analyses how organizational decision-making strategies intertwine with the specificity of their activity, based on executor fiduciary obligations and stakeholder involvement.

Definition

Governance refers to processes of rule whenever they occur (Bevir 2012, p. 29).

Introduction

There is a vast amount of literature covering the concept of governance. Governance is used widely to point to either theoretical underpinnings of governing or to the practice of governing on a local, national, or international level. Pierre and Peters (2020, p. 1) point out that governance is an umbrella concept spanning different meanings from policy networks, public management, coordination of sectors of the economy, to public-private partnerships, and collaboration between public and private organizations. Baseline to all this is that the concept of governance still lacks a unified interpretation (Asaduzzaman and Virtanen 2016; Pierre and Peters 2020, p. 1).

As was hinted in the previous paragraphs, government and governance are related concepts, but they are not the same. Bevir (2012, p. 28) distinguishes between the concepts both on an empirical and on a theoretical level. On a theoretical level, governance is the process of governing by organized (e.g., government) or not organized (e.g., markets and networks) agents. On the empirical level, governance refers to a shift in how public and private institutions have changed since the late twentieth century.

Since the literature on governance is vast, this entry is limited to explaining the concept of governance from various perspectives. This entry starts with the etymology of the word governance and a typical textbook definition of the concept and expands this basic understanding.

Starting Points: Etymology and a Working Definition(s)

The etymology of the word governance is Latin *gubernare* (and Greek *kybernan*), which means “to steer” or “to pilot” (e.g., a ship).

A textbook definition of the term governance includes the following meanings: (1) “the activity or process of governing”; (2) “a condition of an ordered rule”; (3) “those people charged with the duty of governing or governors”; (4) “the manner, method or system by which particular society is governed” (Rhodes 1996). Kooiman (2003, p. 3) at the very beginning of its treatise defines

governance as: “a mix of all kinds of governing efforts by all manner of social-political actors, public as well as private; occurring between them at different levels, in different governance modes and orders.” Furthermore, he points out to the difference between governing and governance saying that: “Governing can be considered as the totality of interactions, in which public, as well as private actors, participate, aimed at solving societal problems or creating societal opportunities; attending to the institutions as contexts for these governing interactions; and establishing a normative foundation for all those activities. Governance can be seen as the totality of theoretical conceptions on governing” (Kooiman 2003, p. 4).

Bevir (2007), a prolific author on governance, points out that the concept of governance gained in popularity in the 1980s and 1990s with the change in how the state governed public institutions. In that period there was an organizational move from hierarchy toward markets, quasi-markets, and networks. This is the context from which the concept of governance is present today in language.

Governance in Contemporary Times

Governance is not a new concept. If looking in the context of governing society or a state, the meaning of the word is probably as old as societies themselves. As long as there are organized groups, there is a need for “guidance,” “steering,” and the “process of rule.” With the development of modern states, the word government slowly replaced the word governance, which was dominant in the medieval period (Bevir 2012, p. 43).

On the other hand, governance relates more explicitly to changes in the state, due to neoliberal reforms, from the closing three decades of the twentieth century. Before them, a structure that was the dominant model of enabling state governance was hierarchy and bureaucracy. As Pierre and Peters (2020, p. 5) explain it: “The State – conceived of as the epitome of the collective interest – was thus distinctly separated from the rest of society but governed society by imposition of law and other forms of regulation.”

From the 1970s the state hierarchic bureaucracy, once believed to be the enabler of social homogeneity, was riveted with a crisis (Bevir 2012, p. 45). The rationale for the mentioned neoliberal reforms was that the state was becoming inefficient in governing when compared with the markets. Thus, the state should create policies but not engage in the direct delivery of services (Bevir 2007).

Bevir (2007), when describing neoliberal ideas, drawing on the work of Osborne and Gaebler (1992), compares making policy decisions (suggested role of the government) and delivering services (not anymore the role of the government) to steering and rowing. The point is that the government is no longer suited for rowing and that delivery of services should be ensured and regulated by the market, competition, and customers. For example, a country might decide to introduce a system where students can choose which school they want to attend and are not limited to a single option of public educational institutions. By creating a public sector to be more like the private, emphasizing more market and network forms of organization, the new governance on both the local and global levels was the result (Bevir 2012, p. 46). The result of such changes would be smaller governments achieved through the privatization of provisioning civil services (Rhodes 1996). As Sharma (2018) puts it, the neo-liberal usages' concept of governance refers to a minimalist state.

Closely connected to the neoliberal reforms and thus to governance is the concept of new public management. According to Rhodes (1996), new public management has two meanings. On the one hand, it refers to managerialism in that the public sector is to be led more like the private with all its characteristics such as performance evaluations, professional management, service to the customer, and similar. On the other hand, new public management also refers to new institutional economics in the context of introducing competition to public service. This approach is more common in the Anglo-Saxon states than in states in the development and transition. Developing and transitioning states started to adopt these ideas only after external pressure (Bevir 2007).

Corporate Governance

Governance is often discussed as "corporate governance." In the expression "corporate governance," governance refers to a system by which organizations are directed and controlled. Rhodes (1996) describes three principles that are applied both to private and public organizations: (1) openness and disclosure of information, (2) integrity and completeness in dealing, and (3) and accountability of individuals for their actions. The principles such as these should be operationalized in organizations.

The principles that he outlined are consistent with principles outlined by the OECD (2015) and the EU White Paper on European Governance (2001). For example, in the mentioned White paper, European Governance is explained through the principles driving forward transparency of institutions and inclusion of the civil society in decision making as well as creating a regulatory framework emphasizing responsibility (*Glossary of Summaries – EUR-Lex* n.d.).

Good Governance

In the economic context, the attribute "good" is often connected with the concept of governance. Such a constructed idea of "good governance" is connected to the efficiency of providing services. The concept of good governance thus emerged in discussions on economic development where institutions such as the International Monetary Fund and the World Bank started using "good governance" as one of their criteria for granting loans (Bevir 2007).

For example, the International Monetary Fund (1997, p. 3) considers two spheres as the aspects of governance that are relevant to them. The first sphere is the management of public resources. This sphere encompasses things like reforms of the public sector and administrative procedures. The other sphere of governance relevant to the International Monetary Fund is the development of a regulatory environment for the private sector. Basically, as Bevir (2007) explains: "The concept of good governance was thus defined by

institutional barriers to corruption and by the requirements of a functioning market economy. It was defined as a legitimate state with a democratic mandate, an efficient and open administration, and the use of competition and markets in the public and private sectors.”

Different international organizations, then the World Bank and the International Monetary Fund, will emphasize different criteria for “good governance” that are more aligned with their purpose. For example, UNICEF might explore “new governance solutions that directly affect child well-being” (*Governance* n.d.).

Conclusion

After reviewing the literature, Asaduzzaman and Virtanen (2016) conclude their treatment of the concept of governance with the following: “(. . .) we can say that the concept of governance applies to multiple forms of collective action. However, it is about more strategic aspects of steering of a society: the larger decisions about direction and roles. That is, governance is not only about *where to go* but also about *who should be involved in deciding* and in what capacity.”

Their findings seem to be aligned with what is presented in this entry. In this overview of the governance concept, we have pointed out that governance is an umbrella term covering both the process of governing and structures that enable rule. Furthermore, governance is different from government. Usually, governance is what the government does in society. Also, governance is the way how organizations are structured. Traditionally organizations are structured in some hierarchical model, but since the end of the twentieth century, new ways of how organizations function and are organized are appearing. This is partly due to neoliberal reforms that have been taking place since 1970s and are in favor of organizing states and state functions similarly to how private organizations are organized. Finally, very often, together with the concept of governance, there are also concepts of corporate governance and good governance. Corporate governance relates to understanding, both theoretical and

practical, how organizations are directed. Good governance often appears in the context of better delivery of services and economic development. In such a context, the concept of good governance is used to emphasize and direct the progress of elements in society, which are essential for the organization, which is assessing the situation.

Synonyms

[Eco-friendly building](#); [Environmentally friendly building](#); [Sustainable building](#)

Definition

Green buildings show high performance while making a low-environmental impact. Several prescriptive certification systems/schemes rate buildings according to compliance with their metrics or points, thus confirm the performance of the buildings they certify. A more flexible and traditional way to build green is to follow guidelines while

considering the environmental impacts of the building. Green building systems can have different aims and priorities; therefore, the metrics and the weight of each criterion are subject to change according to the system, the building type, targeted stage of certification, etc. The systems have not been in place for a long time. The pioneering systems were created by either scientific or professional organizations and started as a voluntary initiative. Yet, the systems have finished their infancy period and solved some of the initial concerns with a flexible structure that encourages innovation, best practices, and ongoing updates; thus, many local or national authorities encourage or require compliance with certain certification/rating systems. The issues of cost and complexity limit the utilization of green buildings. How much they cost must be identified before deciding to use a system. The complexity of the system necessitates experts, who can assess the aim, criteria, or metrics to define goals from the design phase to the postoccupancy phase. While the complexity of a system usually increases with each update, affordable and simpler systems are preferred. Schemes for large scales such as neighborhoods maximize benefits while minimizing costs.

Green Building Rating Systems

Most of the humans are spending a significant portion of their lives indoors; therefore, the building sector is undoubtedly one of the most important industrial and economic sectors that affect the quality of life and the environment. In modern architecture styles, buildings could be evaluated on their own, without showing any regard to their environments. This common approach and rapid urbanization exacerbated many environmental concerns. The most significant concerns are increasing temperatures and changing climate, which necessitate that living conditions and building practices change to adapt to existing and future conditions. Various measures are taken, and policies are implemented for buildings worldwide. Green buildings are known to cause less impact on the environment while providing

healthy and productive indoor conditions; thus, green building/settlement/city concepts are gaining importance and popularity.

The concept of green building has different connotations in different countries and lifestyles. Usually, a prescriptive perspective related to certification schemes comes to mind. The definition in a broader sense includes design and implementation suitable for a sustainable and environmentally friendly lifestyle. For this purpose, there are various examples of good practice that can be seen all around the world. While green buildings were first focused on decreasing environmental impacts of buildings, the issue of sustainability entered and widened the scope. Green building rating systems are one of the most common tools in the attempt to deliver sustainable buildings. The green building rating systems evaluate the performance of a building in terms of certain criteria and provide a certificate.

Getting a green building certification is usually voluntary; however, sometimes countries encourage or insist on green building certification for certain types of buildings by integrating them with building codes or giving them a priority for public procurement. For green building procurement, it is necessary to regulate the procedures and principles regarding the establishment of evaluation and certification systems and determining the duties, qualities, and responsibilities of those who will take part in the evaluation and certification process. More systems are being developed, and existing certification systems are evolving with time. They are developed or maintained by independent organizations. Meanwhile, many countries have their own Green Building Councils that can help with the development or implementation of green building certification systems. On the one hand, many countries have their certification systems, on the other hand, the most common green building certification systems worldwide are spreading by being more flexible or adapting to the local conditions by making specialized certification categories.

The selection of a green building-rating system is significant since all the systems have the same aim of lowering the building's environmental

impacts, yet their ways to reach it vary. Therefore, a system in alignment with the aims of the project must be chosen. The system goals must be similar to the project goals with regards to the building type, the development phase of the project, the environment and site conditions, the applicability and availability of the systems in the area, the suitability, and measurability of the criteria, or opportunities to innovate. The considerations at the design phase include goal setting, integrated design, looking at the project as a whole, life cycle costs, energy modeling, carbon calculations, water use, material use, health concerns, reduction of heat island phenomena, and light pollution. At the construction phase, sustainable construction practices, detailing, and changes during construction and commissioning need deliberation. Yet, at the operation phase metering, ongoing performance evaluation and maintenance require careful thought. The earlier these issues are considered, the higher benefit can be obtained with the least cost.

The certification process starts with choosing a certification scheme and registering. For the most part, the building professionals learn about the relevant documents and upload them to the website before construction starts and continue updating them or marking their progress as the construction continues. The commissioning of the system and the actual performance are also usually a part of the scheme and need documentation. A third party that manages the certificates can inspect the documentation or the actual building. Usually, professionals licensed by the system's authority are the only ones that can perform evaluations, and in some systems they only help, or their presence accounts for more points or compliance. Continuous monitoring and inspection are not usually a part of systems. However, decertification is possible when noncompliance is discovered.

The globally most widespread certification systems include Leadership in Energy and Environmental Design (LEED) from the USA, Building Research Establishment Environmental Assessment Method (BREEAM) from the UK, Green Star from Australia, BQE, Deutsche Gesellschaft für Nachhaltiges Bauen (DGNB)

from Germany, Assessment Standard for Green Building from China, and Comprehensive Assessment System for Built Environment Efficiency (CASBEE) from Japan.

Criteria for Green Buildings

Green building systems rate buildings into usually four to six grades depending on the system. They differentiate between shades of green depending upon compliance or the number of points earned. The main challenge that distinguishes green buildings from initiatives such as zero carbon, zero energy, and nearly zero energy buildings is considering the many issues simultaneously. Therefore, the performance assessment of a building is performed according to the criteria determined by a green building system. Applications will be made based on these criteria; therefore, criteria and subcriteria must be clearly defined. Thus, the development or improvement of a green building system requires discerning the relevant key criteria. For this reason, many researchers evaluate and compare different systems on their handling of a specific criterion, such as “energy,” “indoor environment,” or “water,” while a smaller number focuses on identifying key criteria across many systems. Illankoon et al. (2017) conducted a deductive literature review and found “site,” “water,” “energy,” “indoor environmental quality,” “material,” “waste and pollution,” and “management” to be key criteria.

The criteria and their weights are not fixed and can change even within different versions of a system. Most of the systems have either different categories or weights for different building types such as new buildings, renovations, offices, residential buildings, schools, etc. Some categories also encompass larger areas such as neighborhoods. While there are many valid concerns for sustainable and green buildings, the buildings cannot be considered independent of their sites. Hence their relationship to their surroundings, neighborhood, city, natural environment, and climate is important. Site selection and planning on a larger scale make it possible to create and

implement mitigation and adaptation strategies such as changing transportation options, revitalizing ecosystem services and natural habitats, moderating the microclimate, etc.

The three pillars of sustainability are not equally thought in most of the green building systems. Environmental issues are given the most weight, with “energy” having the highest weight in most of the systems. This concern is because the energy spent for heating, cooling, ventilating, and lighting to provide user comfort in buildings is almost half of the total energy in the world, and buildings are the largest source of carbon emissions; therefore, they can have the largest impact on global emissions in the most cost-effective way. Mass, orientation, building materials, and cooling and heating needs of buildings, and the climate are the primary considerations associated with energy use and greenhouse gas emission levels. Moreover, global emissions in urban areas can be reduced by up to 58% by 2050 with only measures taken in buildings (Colenbrander et al. 2019). However, there is a significant gap between design and operational consumption as in the case with conventional buildings. Hence, although green buildings usually perform better than conventional buildings, they do not perform as well as expected.

The second most prioritized issue through systems is “indoor environmental quality,” which encompasses subcriteria related to human health and well-being, and most of the social aspects in the systems. However, the criteria extremely vary between systems and applications in countries; therefore, it is hard to infer general principles (Thatcher and Milner 2012). Also, both objective measurements and subjective surveys are simultaneously applied or one of them is used to evaluate occupant satisfaction of green buildings, showing that the results for green buildings are better than conventional buildings mainly because occupants are more tolerant of green buildings (Geng et al. 2019). El Asmar et al. (2014) point out that the buildings can perform better than indicated by the LEED certification as the certification process focuses more on design and construction issues, rather than the occupation phase.

Other socioeconomic and environmental aspects include more efficient use of “materials” and “water.” Besides, the “waste” generated from construction and demolition activities also accounts for around one-fourth of global waste, meaning reduce, reuse, and recycle principles (3Rs) can be utilized to manage waste. Yet, “management” is not a separate criterion in most of the systems. However, sustainable management practices also aim to reduce the environmental impact of buildings, and their principles are similar to green building criteria (Alfalah and Zayed 2020). A further discussion of Illankoon et al. (2017)’s key criteria show that they cover more than 93% of the credit points for seven common international systems. Yet, nearly a third of the credit points for CASBEE were not covered by the key criteria, especially region-specific targets such as “earthquake resistance.”

Each green building system has its guidelines and checklists to instruct the relevant actors, such as developers, designers, planners, engineers, and suppliers. The systems can use simple checklists or complex calculations to take many considerations into account. The rating systems often refer to local building codes and regulations, and other specialized standards and product certifications during their processes. Some examples include compliance with environmental management (such as ISO 14000 Series) or energy management (ISO 50000 Series).

The systems can also have different priorities for different building types such as residential, commercial, healthcare, educational, and existing buildings. Another consideration is the scale of the project, the issues of a district or neighborhood development can also be regarded. In contrast to prescriptive systems, toolkits such as SB Tool provide a flexible framework to develop green building systems per the necessities of the users.

Most of the changes related to the climate and sustainable development goals agreed by the whole world must occur in the building sector, and the building sector should lead these changes. Significant issues for sustainable design and practice such as urban heat island phenomena, embodied energy, ecosystem services, and education and awareness are usually not addressed. In this

context, economic aspects are not prominent in green building rating systems, since this aspect has the lowest number of dedicated criteria (Park et al. 2017). But, revising existing green building systems to add other criteria and expanding them with continuous updates are both possible and accepted practices.

Economic Aspects of Green Buildings

Green buildings cannot be considered independent of costs since the cost is very important for sustainability in the construction industry. The initial cost of green buildings is assumed to be higher than normal buildings because of costs associated with certification including costs for registration, consultation, added implementations, and certification. These costs are paid by the building owners or developers, while third party institutions issue the certificates based on their declarations and calculations. Also, integrated design, certification, and sustainable construction processes can add more time and associated costs to the building.

It should be noted that the perception that a green building necessarily costs higher is a misconception. The general trend in the construction industry is to keep the initial investment costs of buildings low; as a result, the maintenance and energy costs rise; thus, the life cycle cost of the building increases. When the cost, thermal and visual comfort, and energy efficiency analyzes are done considering their life cycle, the evidence of green buildings being more expensive is inadequate. While the higher rating of a green building usually corresponds to higher implementation costs (Kats 2003), which is the main cause for higher initial costs, the cost of a green building decreases with the spread of green buildings and green building technologies. Moreover, claims of lower maintenance costs and additional benefits such as better health and fewer absences signify that building green is an economic option, and an evaluation about certain sustainability-related characteristics can be added to valuation reports (Lorenz and Lützkendorf 2008). However,

optimization of life cycle costs for the considered case is necessary.

Green building design is similar to good design, so the question of “what kind of benefits does being a green building get?” arises. High initial costs make green building investments undesirable for landlords and developers. While tenants may find green buildings attractive because of advertised lower operational costs and higher comfort, the results of studies comparing green buildings and conventional buildings in terms of value and rent prices are ambiguous and change between building type and country. Yet, Ambec and Lanoie (2008) made a systematic review of the literature and report that there is a paradigm shift from environmental protection being a burden to it being a necessity in the industry since environmental and economic performances are positively linked. Thus, many incentives, grants, financing, and government initiatives encourage or require compliance with sustainable and green building criteria.

Summary

The significance of environmental problems is becoming more evident these days. Meanwhile, green buildings look for opportunities to improve outdated practices. And the research about green buildings reports many beneficial environmental impacts including decreasing urban heat island phenomena, decreasing resource and water use, reutilizing wastewater and resources, decreasing emissions to air and water, improving indoor air quality, improving waste management, improving the site environment, making use of green/blue infrastructure and building elements, and disseminating best practices. Therefore, it becomes imperative that normal construction practices follow the way of green buildings. However, since all the systems must balance several issues, they can be criticized depending on their focus being on energy consumption, indoor environmental quality, or economic factors instead of other significant issues.

There are many systems and ways to build green; therefore, choosing the way forward is the

key issue. The goals of the project can be selected according to the building type, the development phase of the project, the environment and site conditions, the applicability and availability of the systems in the area, the suitability and measurability of the criteria, or the opportunities to innovate. The earlier these issues are considered, the higher benefit can be obtained with the least cost. Green buildings can either follow a prescriptive methodology to get a certification or follow more traditional and flexible guidelines in harmony with the natural environment. Achievements so far have shown that “green buildings” are not just conveyed by following prescriptive rules, but by supporting sustainability goals, and improving users’ quality of life. As such, being prescriptive is a point of criticism.

Performance criteria and weight percentages of the criteria are necessary for the development of new systems and assessment of existing systems. Evermore stringent environmental targets are imposed over time. The additional expenses and expertise limit the spread of green practices; therefore, more affordable and simpler systems can make green buildings more accessible to the masses. Green buildings usually have higher initial costs than conventional buildings as the rating of the green building goes up. Yet, as the number of green buildings increases, so does the number of available and affordable technologies; thus, their costs decrease. Besides, systems that utilize green buildings and green building principles in bigger scales such as neighborhoods are spreading. Many cities in the world have begun to show how cities can transform with good public transport, green public spaces, and resilient infrastructure. Thus, green buildings are an important tool for the future of urban development.

Circular economy

Definition

According to the Ellen Macarthur Foundation (2013), the circular economy consists in: *“Looking beyond the current take-make-dispose extractive industrial model, a circular economy aims to redefine growth, focusing on positive society-wide benefits. It entails gradually decoupling economic activity from the consumption of finite resources, and designing waste out of the system. Underpinned by a transition to renewable energy sources, the circular model builds economic, natural, and social capital.”* Recently, many policy makers have started to pay attention to this new operational paradigm. Specifically, the attention has been driven from the exigence to mitigate the risks of climate change.

The wide adoption of this new organizational model has been characterized by several criticisms by private firms due to its organizational implications. In fact, as evidenced by the Ellen Macarthur Foundation, an effective transition to this new paradigm represents *“a systemic shift that builds long-term resilience, generates business and economic opportunities, and provides environmental and societal benefits.”* Moreover, some researchers have identified internal and external enablers and obstacles to the adoption of circular business models. In this sense, a central role will be covered by policy makers in order to support the voluntary adoption of more sustainable business models by worldwide firms.

The Circular Economy Paradigm

The evolution of our industrial economy has been dominated since the early days of industrialization by a fundamental characteristic: a linear model of resource consumption called “take-make-dispose.” The companies collect and extract raw materials and use them to make a product; they then sell the product to consumers, who throw it away when it no longer performs the function for which it was purchased.

This system worked well until the end of the last century because the low cost of resources, traditionally considered abundant, supported economic growth in the most advanced countries. The reuse of materials, more expensive than the use of virgin material, was therefore not a reason to exist from an economic point of view. Today, however, the commodity market is much more volatile and the prices of so-called “commodity” goods, fundamental elements for industry, have risen sharply over the past few years. Because of this, many companies and many countries are starting to modify their industrial model so as to be less dependent on those resources that are becoming increasingly scarce; the transition is made even more urgent by the fact that demographic trends indicate a growth of the world population in the next 30 years of more than 2 billion people.

Environmental issues are certainly not new to the world of economics and industry, and important strides have been made in this regard. However, focusing exclusively on increasing efficiency while remaining in a linear perspective can only delay the inevitable consequences of finite resources. In this sense, academics (Haas et al. 2015) have shown how only 6% of all materials processed by the global economy are recycled and contribute to closing the loop. Furthermore, the authors denoted how the EU-27 are slightly above the global averages.

Nowadays, an increasing number of scholars have started to identify a new operational framework in order to favor the adoption of a new form of business models by the enterprises.

Furthermore, the exigence to align firms' strategies to SDGs has supported the evolution of this new field of study (Schroeder et al. 2019).

According to Lüdeke-Freund et al. (2019), the systematic analysis of the current literature about circular economy reveals the existence of six different types of business models theoretically related to the circular economy paradigms. The six types of business models are as follows: "Repair & Maintenance," "Reuse & Redistribution," "Refurbishment & remanufacturing," "Recycling," "Cascading and repurposing," and "Organic Feedback." Furthermore, an analysis performed by Pieroni et al. (2019) on a cluster of 92 research papers has highlighted the exigence to develop new studies about circular economy in order to identify new tools useful for an effective transition to this new approach.

Another theoretical classification defined "ReSOLVE" was introduced by the Ellen MacArthur Foundation (2015). The ReSOLVE represents one of the main frameworks used to assess the degree of circularity of a business model. Building on the idea that circularity can be achieved through different strategies, it consists of six approaches, which are synthetized by the following items: regenerate, share, optimize, loop, virtualize, and explore. The six dimensions are characterized by a high degree of dependency due to the need to adopt a holistic approach based on the integration of different processes. Thus, even in the absence of a direct connection with them, organizations will impact positively or negatively on all the six dimensions through their actions (Manninen et al. 2018; Yadav et al. 2020).

Nowadays, practitioners have started to evidence the strong relationship between circular economy and climate change. In particular, this evolution has been driven from the Ellen MacArthur Foundation (2019) which covers historically a central role within the debate about circular economy. In this sense, the concept of "circular economy" will be characterized in the next years for further changes in order to identify a new form of paradigm useful for the achievement of a highest degree of worldwide sustainable development.

Summary

The increasing stakeholders' pressure about sustainable development has imposed to firms, practitioners, and policy makers the identification of new paradigms. Currently, many firms have started to adopt voluntarily a new form of business models inspired by the circular economy's paradigms. Their contribution will be relevant for the achievement of the SDGs. In fact, one of the main innovations which characterize SDGs is represented by the explicit call in action of the private sector. However, nowadays, only a few parts of the worldwide firms have started to adopt circular's business models. In this sense, in the next years, the policy makers will identify a new form of policies in order to sustain the circular economy paradigm. Finally, the contribution of the academics will be determinant due to the lack of evidences about this new form of business model.

Definition

Green economy is an economy that combines bioeconomy and social justice principles in the pursue of ecosystem resilience and human well being.

Introduction

Green economy refers to an economic system that in the words of the UN “aims at improving human well-being and social equity by internalizing its environmental impacts and significantly reducing ecological risks and scarcities.” The founding principle of the green economy is that the search for a reduced dependence on natural resources drives innovation capabilities towards the reduction of hidden diseconomies, the use of renewable inputs, and a higher systemic resilience that provides a better quality of life for all within the ecological limits of the planet.

Green economy has a complex and science-based nature, because the correct interpretation of the different interests at stake requires a rigorous and objective understanding of social, economic, and environmental phenomena.

Despite the fact that there is no internationally agreed definition of green economy, in recent years, green economy principles have been widely adopted and green economy has emerged as a strategic priority for many governments in their pursuit of sustainable development. In fact, it provides a conceptual framework that helps identifying and investing in environmentally friendly and socially equitable solutions that link economic, social, and environmental considerations and help achieving long-term economic development.

Green economy shares the orientation toward profit and value-creation which are the cornerstones of more traditional – and still dominant – forms of the economy. Despite that, it introduces a previously suspended commitment to inclusiveness, equality, and waste prevention that is relevant at both micro- and macrolevels. While traditional economies represent a threat to the attainment and maintenance of a healthy environment and equitable access to ecosystem services and do not guarantee a fair allocation and management of externalities, which are all crucial aspects of sustainable development, green economy aspires to do the opposite and to increase the legitimacy and attractiveness to investors of greener products and services.

History

Starting in the 1960s, scientists began demonstrating that continued human population growth, combined with increased human affluence, was outpacing technological efficiency improvements in the long term and, thus, harming the sustainability of the mainstream development model.

Grounding on this debate, the term “green economy” was introduced by economists in the late 1980s, not least to facilitate dialogue with policy makers on the inner nature of sustainable development and its implications for the economy. Among the first documents that mention this term are the 1989, 1991, and 1994 reports for the UK government by Pearce, Markandya, and Barbier entitled, respectively,

“Blueprint for a Green Economy,” “Greening the World Economy,” and “Measuring Sustainable Development.”

Following these early contributions, the concept of green economy became widely used first in the debate on the contribution that industrial economy should offer to environmental policy and then to analyze the economic origins and consequences of problems such as climate change, deforestation, ozone depletion, and resource loss in the developing world. In particular, the term became popular in the scientific community engaged in an attempt to operationalize ecological economics theories (Shmelev 2016) and propose a reformulation of the concept of firm competitiveness.

By virtue of increasing scientific support and the UN push for “green stimulus packages,” the concept of green economy rapidly became central in the policy debate. Not surprisingly, it also became also a cornerstone of the policy response to the financial crisis and concerns of a global recession in late 2000s.

In 2008 the United Nations Environment Programme (UNEP) launched its Green Economy Initiative to provide analysis and policy support for investment in green sectors and for greening environmentally unfriendly sectors. Through this initiative, UNEP ensured global research and country-level assistance encouraging policymakers to support environmental investments within the context of sustainable development.

In 2009 UNEP published a report entitled Global Green New Deal (GGND), which condensed a mix of policy actions that, also by means of a clear directionality to stimulus funding and targeted and appropriate fiscal and social protection policies, would help foster economic recovery and, at the same time, improve the sustainability of the world economy.

In the same year, the UN General Assembly asked the Nobel laureate economist Joseph Stiglitz to chair a commission that was established to examine reforms of the global financial and monetary system. Similarly, the Gates Foundation contributed to the 2011 Cannes G20 Summit with a report on innovative financing mechanisms for development (Barbier 2012).

As scientists formulated the rationale for investments in the green economy as a means to address a variety of concerns including the food crisis, energy crisis, water scarcity, biodiversity and ecosystem loss, climate security, and desertification (Gouvea et al. 2013), several concepts such as sharing (see ► [“Sharing Economy”](#)), circularity (see ► [“Circular Economy”](#)), collaboration, solidarity, resilience, opportunity, and interdependence became representative of related operationalization pathways. Evidence of the structuration of this extended taxonomy can be found in the UN Environment report “Uncovering pathways towards an inclusive green economy,” published in 2015.

From that moment on, green economy was acknowledged as a conceptual framework that legitimates an increasing number of tools for achieving sustainable development, sometimes even with a specialization on specific topics, like in the case of the focus on climate change in international summits such as the UN Climate Change Conference in Copenhagen and the 2012 UN Conference on Sustainable Development (Rio+20).

As highlighted in the Green Economy Report released by UNEP in 2011 under its Green Economy Initiative, the worldwide popularity of green economy is constantly increasing, with no countertrends and, over the past decade, it has emerged as a strategic priority for many governments and intergovernmental organizations.

In 2011, the UN Environment Management Group released the report “Working Towards a Balanced and Inclusive Green Economy” which is a system-wide perspective on green economy that, by systematizing the main experiences of countries that have embarked on a path of transformation of their economies into drivers of sustainability, identifies and clarifies the use of green economy and other related terms in different contexts. Besides the aim to define the major challenges of this century, this report represents the first systemic update of the taxonomy of the phenomenon that, leveraging an increasing number of experiences, will provide a progressively clearer understanding of the interrelated dynamics in the operationalization of the above-mentioned

sharing, circularity, collaboration, solidarity, resilience, opportunity, and interdependence. The need to classify green economy initiatives, which nowadays cover many diverse concepts at different levels of intensity, is widely recognized as a continuous exercise aimed at capitalizing on the learning process to improve understandings of the different degrees of substitutability and trade-offs between environmental and economic benefits (Loiseau et al. 2016).

General Principles

In a broader view, green economy emphasizes opportunities to advance both ecological and social performance as drivers of a prosperous financial system. This means giving green investments an increasing legitimization among traditional economy actors not just because of the widely felt sense of urgency of searching for alternative pathways to achieve the goals of the 2030 Agenda for Sustainable Development (Dittmar 2014), but also because of the actual possibility of ensuring an inclusive and long-term generation of added value. From this perspective, green economy provides attractive directions on how to leverage an inclusive life-cycle perspective, which accounts for a variety of dimensions ranging from ecology to jobs, fairness, social inclusion, income, and health, in the development of strategies with the ambition to pass the test of environmental, social, and economic sustainability.

Inclusiveness is a key concept that refers to the minimization of negative impacts throughout the lifecycle of products and services through a multi-stakeholder and trans-generational approach. Inclusiveness is thus an ambitious goal that requires synergies among industrial, environmental, and social policies built on the coordination of a variety of interventions that include green funding, procurement, tax and regulation, monitoring and reporting, process and product standards, incentives, capacity building, and awareness raising campaigns. By leveraging the economic, social and environmental rationales for waste reduction, eco-innovation, resource

efficiency, and use of renewable sources, the resulting policies are expected to foster a radical transformation of entire industries by thinking out of the box to find how to radically change existing unsustainable, or weakly sustainable, processes. As an example, the second principle of green chemistry, i.e., “synthetic methods should be designed to maximize the incorporation of all materials in the process into the final product,” shows how waste and hazardous material management policies can push scientists and practitioners to rethink the concept of efficiency in chemicals manufacture towards the use of just what is necessary and under control (Sheldon 2016).

Inclusiveness also highlights a nontechnocratic orientation. The green economy approach is intrinsically multidisciplinary, offering solutions from technological innovation (which is relevant to unlock a new and more efficient relationship between progress and the use of resources) to psychology (which is relevant because of the need to achieve lasting behavioral changes) (Borel-Saladin and Turok 2013). As a consequence, green economy does not involve standardized implementation of social/environmental product/process techniques or management systems. Nor is it just about conformity to standards to obtain labels, e.g., based on the measurement of carbon and environmental footprints. Since the most marginalized or vulnerable groups are often particularly exposed to environmental hazards at home and at work, green economy is instead a creative tension towards new ways to firstly account for multiple stakeholders’ perspectives on the substitution of nonrenewable and hazardous chemical materials, the creation of green jobs (Smit and Musango 2015), and the contribution to holistic conservation of natural resources and ecosystem services. This means that, as an example, a low carbon economy based on the use of renewable energy and materials fully complies with green economy principles only if, on the one hand, it promotes synergies with interventions aimed at increasing resilience to climate change and, on the other hand, it also takes into account the related ecosystem and social changes, and the residual tradeoffs with economic sectors that

directly depend on biological resources such as agriculture, forestry, and fisheries (Gasparatos et al. 2017). Similarly, introducing solar power generation into traditional production processes is still not green economy, for which it is necessary to ensure – among others – responsible sourcing and end-of-life management of the photovoltaic cells, so as to avoid often disregarded life-cycle impacts in remote areas. To this end, the reformulation of value propositions and business models enabled by holistic investigation of the product/service value chain are typically a necessary amendment to traditional technocratic and efficiency-driven formulations.

The Variety of Approaches for Green Economy Implementation

Because of its multifaceted nature, turning green economy into action is a complex task. The outcomes of green economy policy vary from simple limitations of the “action space” of the brown economy (Droste et al. 2016) to green initiatives that, depending on their extension and depth, lead to incremental or radical changes in traditional industries (Marcus et al. 2016).

Given its inclusive and holistic goals, green economy more likely challenges entire supply chains than single firms. It thus should be considered that the greening of supply chains is an evolutionary process that cannot be fully planned from a deterministic perspective, but requires preserving a variety of competing alternative solutions, so as to avoid the introduction of lock-ins and the waste of tangible and intangible capital (Rizzi et al. 2013). Since going green should be considered a trial and error process, it is not surprising that the resulting variety of heuristics has still not provided the large number of governments on the planet that have adopted green economy policies in the two decades (i.e., since the first Rio Earth Summit) with a clear and standardized way to address “sustainable development” (Dittmar 2014).

Heterogeneity in implementation approaches is evident when looking at the number of alternatives that stem from the convergence of social

capital, natural capital, and life-cycle perspectives in full cost accounting. As an example, the International Monetary Fund has introduced a “Green Fund” initiative to stimulate responsible global monetary policy that moves towards biodiversity valuation and a more official and universal means of biodiversity finance. Others, like the Zero Emissions Research and Initiatives, target not less but radically zero emissions and waste. The International Chamber of Commerce (ICC), instead, promotes green economy initiatives with a primary target on the mutual reinforcement of economic growth and environmental responsibility to support progress on social development via a consolidation of open and competitive markets. Even the scientific community tends to refer to the green economy as resource-focused, whereas in principle it should acknowledge the underpinning role of all ecological processes and should be more inclusive of salient social aspects at the local level (D’Amato et al. 2017).

More generally, the structuration of the discourse on green economy presents a variety of interrelated priorities and patterns that depend on the different foci on such polar concepts as scarcity or limits, means or ends, and reductionism or unity (Bina 2013). Despite their differences, all the emerging approaches converge to enabling a related variety of initiatives that contribute to drive global investments toward the overall annual financing demand to green the global economy.

In this context, the European Union (EU) green economy policy presents one of the most comprehensive coordination efforts in linking together growth, job creation, poverty reduction, natural capital investments, transaction taxes, cleaner technologies, energy and resource efficiency, low-carbon development, innovation, the use of ICT, and both the local and global reduction of unsustainable uses of natural resources. To this end, the EU view the green economy from a macroeconomic perspective to promote overarching, instead of fragmented, policies. The basic assumption is that filling the knowledge gaps that are necessary to enable the shift towards green economy requires, in line with the Porter hypothesis (Porter and Linde 1995), an

increasingly spontaneous commitment of private resources to pursue the triple bottom line (see ► [“Triple Bottom Line”](#)) in all industries and at different levels. Such spontaneous commitment should be driven by the expectation of reasonable benefits and achievements in term of competitive advantage. The resulting coordination of policies for sustainable development thus consists of a broad set of interventions that go beyond government action to involve the private sector. These interventions target, in particular, the creation of the enabling conditions (e.g., re-skilling of the existing workforce) that correct market and governance imperfections and failures and the introduction of suitable economic incentives to producers and consumers to pursue a green, clean, low-carbon economic trajectory. As new technologies are necessary to cope with availability, safety, quality, and security of scarce resources (Gouvea et al. 2013), since the initiation of the Horizon 2020 program, the EU has coordinated green policies with large-scale research funding frameworks. This encompasses different levels of technological readiness, including the demonstration of the business case for lighthouse experiences, in which costs externalized onto society via ecosystems are reliably traced back to, and accounted for as liabilities of, the entity that does the harm or neglects an asset. This is, in fact, considered a key mechanism for boosting eco-entrepreneurship and supporting people in starting their own green business and thus in increasing opportunities to improve their standard of living. Workshops and online and offline opportunities for storytelling have been widely used to promote the spreading of successful experiences as well.

There is thus increasing acknowledgment of the importance of both the technological and non-technological nature of green initiatives. Thus, nowadays, not surprisingly, to promote a green economy, the emergence of charismatic leaders is needed to escape from the threat of a deadlock due to the resistance to change of incumbents, which limits the capability to seize win-win opportunities, together with systemic perspectives and skills in negotiation and inter-organizational planning strategies (Rizzi et al. 2014). Besides

charismatic leadership, as trust carriers, certifications and ecolabels are often considered a reliable way to provide a third-party demonstration of the actual performance of green investors and, thus, to boost the replication of greening practices in a globalizing economy.

Of course, green economy is not free from shortcomings. The lack of firm commitment of world leaders to the principles discussed in the Rio+20 summit shows how difficult orchestration is at the global level. Skeptics highlight that its metrics are still in dispute, and there is uncertainty on the relationship between actions and the size and timing of the benefits for humans and ecosystems. Even more, while these benefits are often global, the efforts are typically highly visible and local, while the internalization of externalities and the correction of market failures through measures that might pay for themselves are still not fully proven at large scale (Borel-Saladin and Turok 2013).

Still, green economy is nowadays the most ambitious, articulated, and lofty effort to harness scientific knowledge and capabilities in an attempt to steer traditional economies towards a sustainable future. Regardless of implementation difficulties, green economy principles are destined to be remembered because there is no way to escape the dependency of human beings on ecosystems.

Synonyms

Ecological economics; Low carbon or decarbonised economy; Natural capital

Definition

The green economy is regarded as an economy that has the goal to reduce environmental dangers and ecological shortages and aims at sustainable development, avoiding environmental degradation (Ocampo et al. 2011; UNEP 2011). In other words, the green economy is the result of greater human well-being and social fairness, considerably diminishing environmental risks within the ecological boundaries of the planet.

The United Nations Environment Programme (UNEP) approach to the green economy is a demonstrated approach, to classify change as

transformative and to distinguish some drivers of change (technological, economic, and ideological), despite being analyzed in an OECD context (Lederer et al. 2018), where there is few organized and compared information about socio-technological changes in developing country contexts. The green economy has become integrated into the economic growth agendas at the national level, frequently joined by arguments that give more easy green economy agendas interpretations for economic growth and market freedom (Caprotti and Bailey 2014).

The exam of the green economy cultural-economic construction is a possible analysis of the green economy perspective and has a neoliberal sense as it aims to place market logic as a key point of sociotechnical transitions to sustainable and low-carbon futures (Caprotti and Bailey 2014). This ecological modernization and green growth approach assume that transformational change comes bottom-up and thinks that economic transformation in the form of economic development can lead to green changes (Lederer et al. 2018).

Despite this perspective might be a strong interpretation of the green economy, a closer analysis of environmental resources management could bring different alternatives to the meaning of the green economy (Caprotti and Bailey 2014).

Introduction

In the last years, the concept of green economy has gained importance, politically and in business, since it was considered one of the central themes of the Conference of Sustainable Development, of the United Nations, in 2012 (Caprotti and Bailey 2014). In addition, as the European Union definition states, green economy is the “economy that can secure growth and development, while at the same time improving human well-being, providing decent jobs, reducing inequalities, tackling poverty and preserving the natural capital upon which we all depend” (DGICD-EU 2018, page 1), which promotes a pathway for sustainable development in a paradigm shift that not focus on economic growth as the ultimate goal but instead

in this driver of growth based on greener policies, market, and business practices, recognizing that resource efficiency and natural capital are the focus for the economy in the long run (DGICD-EU 2018). Therefore, the green economy, in different approaches, was promoted to catalyze national policy development and transnational collaboration toward sustainable development, poverty eradication, intragenerational and intergenerational even-handedness, enhanced economic performance and fair use of resources (Caprotti and Bailey 2014; Allen and Clouth 2012).

In this perspective green economy is a compatible concept with the sustainable development one, but it also implies some dangers and questions. There is the fear that this concept reinforces protectionist trends, boosts the constraints linked with financial international cooperation, and makes available new forces that would reinforce international inequities (Ocampo et al. 2011).

It was highlighted market-based trajectories to accomplishing the transition to the green economy and asked for close cooperation between government and business to achieve this greener and resource-efficient economy perspective. These trajectories involve combined study in order to reach knowledgeable research on the deficiencies and potentialities of the green economy (Caprotti and Bailey 2014; Khor 2011).

This article pretended to discuss the green economy concept and the main implementation items such as the main sectors to develop, indicators, and a roadmap designed to achieve it. Considering that the goal of the article is on concept definition, it will begin with the main perspective of the green economy concept and discuss the main approaches to accomplish it.

The Concept of a Green Economy

The term green economy was first used, in 1989, in a report produced by a group of environmentalist economists titled *Blueprint for a Green Economy* (Pearce et al. 1989). In 2008, the term was reused within the discussions on the political response to the multiple global crises. In

consequence of the financial crisis and global recession concerns, UNEP defended the idea of “green stimulus packages,” and some specific areas were pinpointed to be supported with a large-scale public investment that could relaunch a “green” economy (Atisson 2012).

This concept, in its broader perspective, has a holistic character and incorporates the three pillars of sustainability-sustaining and sustainability-promoting economic, environmental, and social welfare and its focus on intergenerational equity (Ocampo et al. 2011). It seems that, like sustainable development, the concept of the green economy is an oxymoron which intends to deal with partly contradictory, different interests and strategies, giving them a certain legitimacy and coherence (Brand 2012).

The Organization for Economic Cooperation and Development (OECD) members, in 2009, embraced the green growth economic policy as its long-term strategic course until the years 2030 and 2050 (Porfiriev 2013). As Brand (2012) stated, the European Union (EU) considered it important to attempt to decrease the use of resources and increase their efficiency since they were the main instruments for handling environmental problems and resource scarcities and improving European attractiveness. The EU’s plan goes in the same direction as the Green Growth Strategy of OECD, which supports the reinforcement of both economic and environmental policies and emphasizes innovation to uncouple development from natural capital reduction (OECD 2011).

The United Nations Department of Economic and Social Affairs (UNDESA) presents the notion of the green economy as a different development paradigm, in a huge technological change by scaling up clean technologies, waste reduction, and sustainable farming (UNDESA 2011). This perspective implies a paradigm shift, such as the concept of sustainable development. In a society where economic growth is still concentrated on measuring GDP (gross domestic product), above any other indicator, the green economy will compel to include other concepts and indicators for the analysis and discussion of economic growth, as the green economy aims to be low carbon,

resource efficient, and socially inclusive (UNEP 2011). This paradigm shift represents a problem since it's impossible for businesses in a global scenario of resource-intensive production and consumption patterns to engage easily in a new paradigm (Brand 2012).

This proposal of another paradigm that promises evolution while shielding the Earth's ecosystems, which is based on improving the quality of life of people consistent with sustainable development, designs a trajectory, departing from the system that originated problems to happen and addressing proactively those issues and to prevent them (Ocampo et al. 2011). This paradigm shift will still take some time to be realized, even if several countries already present some programs that indicate the demand for green growth or economic low carbon strategies. Our history shows some structural constraints where dominant economic and political forces present difficulties to be weakened regarding these proposals of the green concept (Brand 2012). This skepticism that Brand (2012) states is not only due to the existing political strategies in guiding the governments toward global competitiveness and geopolitical interests, in a free trade scenario performed by powerful institutions, but also because market and profit drive development technologies will ensure the promotion of sustainability, particularly in a dominant social orientation development without regarding the risks, the increasing exploitation of nature with power relations unbalanced, and reluctant to lose control.

The risks of this perspective of concept pointed out by Khor (2011) are the one-dimensional manner, purely environmental, without fully reflecting the development, equity, and the international dimensions; its "one size fits all" perspective, in which all countries are treated in the same way and it should take into account the country levels and phases of progress and the urgencies and settings of developing countries, considering the principle of differentiated; the inappropriate use of the environment and/or the green economy for trade protectionist means (e.g., imposing of "carbon taxes" or "border adjustment tax" on products); misuse of environment claims as a masked way by countries to endorse the access of their

goods and services into international markets; subsidy attribution on the more rich countries to the research and development (R&D) of environmentally sound technologies which puts other countries in disadvantage, especially since they lack the financial resources; implementation of environmental canons for products that some countries are incapable to meet the canons face losing their exports; and use of green economy claim as a condition to access for support, credits, and debt rescheduling or relief to countries. Therefore, there is a necessity to detect and deal with the trade-offs that may be involved at different phases of progress and with different environment capabilities and trials.

Another definition of green economy and in a narrower conceptualization, when seen as the inclusion of the economic activity styles and goods that contribute to the increased life quality and living environment while also transforming the manufacturing process and making it more efficient. So, it's considered as the development, production, and technology and equipment use that diminish pollutant emissions and greenhouse gases, monitor and forecast climate change, and create resource conservation and renewable energy technologies. Other features of the green economy can also be included, such as design and technology use; materials that shield buildings from wide temperature variations, humidity, and wind; and manufacturing of environmentally friendly products, specifically consumer goods (like medicine and household essentials that contain no chemical additives) and agricultural products (foodstuffs and natural fibers) (Porfiriev 2013).

Green Economy and the Economic Growth

The green sector of the economy is characterized by exceptionally rapid growth, especially relative to the general economic slowdown of 2008–2012 that can be explained, mainly, by three factors: the first two are very related to a clean and safe environment and the risk minimization of climate change, since green technologies have fewer

risks and are smaller in scale than twentieth-century industrial technologies, and a third factor is the concentration of scientific research and the high level of technological development of green enterprises that enable the faster transition to the new (sixth) wave of innovation (Porfiriev 2013).

To meet the challenges of increasing economic growth and awareness of the ecological limitations of global development, already noticeable climate change, and increasing social inequalities, UNEP and other institutions, like OECD and EU, agreed on the concept of a green economy as the driver for more sustainable growth of the economy and society (Lederer et al. 2018; UNEP 2011). This concept is interconnected with the concept of sustainable development since it acknowledges and reflects its concerns and incorporates its three pillars (economy, environment, and society), giving a highlight to how the environmental policies help to achieve sustainability at a low cost (Zhou et al. 2018). A green economy emphasizes an efficient and functioning economy needed to achieve progress and has an optimistic view of the technological innovation and market instruments to make the economic sectors greener (Lederer et al. 2018; Pegels et al. 2018).

To achieve its goals, this green economy concept calls for governments to take more direct responsibility and intervention in the economy to guide (in the form of subsidies, formulation and implementation of green policies) and promote the changes needed within the social and economic paradigm (Lederer et al. 2018; UNEP 2011). According to projections until around 2050, most countries will experience rapid growth and a visible increase in the green energy sector in general with emphasis on the green energy sector (Porfiriev 2013). Solving problems through a variety of institutional and regulatory reforms, tax-based and cost-effective economic policy and tools (OECD 2011) can be a path.

The key challenge is how we can move in the direction of an economic system that will benefit more people in the long term. Making the transition to a green economy will require a major change in thinking about development and expansion, the production of products and services, and consumption habits, as has already been said. This

shift will not happen merely because of better knowledge of effects, dangers, or economic study despite the acknowledgment of being one of the best answers to global crises, especially in managing social and environmental issues (Andreica et al. 2014).

Several sectors are considered key for the 2% of global GDP investment advocated by UNEP to achieve green transformation with national and international political reform drivers: agriculture, buildings, energy, cities, fisheries, forests, industry, water, tourism, transport, and waste management (Andreica et al. 2014).

In the map shown in Fig. 1, the green business sectors are grouped into several categories, based on an analysis of the industries in the UNEP report. The darkest shades represent the areas most referred of every industry sector in the report within the range of the traditional business (vertical axis) and of the business related to production and consumption issues (horizontal axis). It's also possible to visualize the influence of government, universities, nonprofit organizations, trade unions, professional associations, and regional innovation systems, at the bottom of the figure. Other ways to make the transition to a green economy have also been defined. Karl Burkart (2012) argues that the green economy should be based on six sectors: renewable energy, green buildings, sustainable transport, water management, waste management, and soil management. These sectors will be the pillars of future growth and sustainable development to achieve.

To access the green economy, a framework of indicators was created by OECD to regularly monitor the progress and status of green growth, following three main areas (Tóthné 2014): green conversion of important areas, the economic investment and their related consequence in production and service; "decoupling and efficiency" to measure resource efficiency and productivity and the uncoupling of economic activity from resource use and related environmental impacts; and combined indicators of development and well-being mentioning various initiatives.

Each country may select and prioritize a different set of indicators (shown in Table 1) depending on its level of economic development

Green Economy II, Fig. 1 Sectors of the green economy. (Source: Adapted from Andreica et al. (2014))

Green Economy II, Table 1 Selected green indicator groups and topics

Indicator groups	Indicators
Environmental resources, economic productivity	Carbon and energy productivity Resource efficiency: material nutrients, water Multifactor productivity
Natural assets	Renewable stocks, nonrenewable stocks Biodiversity and ecosystems
Environmental dimension of quality of life	Environmental health and risks Environmental services and amenities
Economic potentials and policy responses	Technology and innovation Environmental goods and services International financial flows Prices and transfers Skills and training Regulation and management Approaches
Socioeconomic context and characteristics of growth	Economic growth and its structure Productivity and labor market, education, income Sociodemographic patterns

Source: Tóthné (2014)

and natural resource usage ratio, and other indicators can be added if important and relevant, as occurred in recent years (http://www.oecd.org/environment/indicators-modelling-outlooks/Highlights_Green_Growth_Indicators_2017.pdf).

The International Chamber of Commerce (ICC), when publishing the Green Roadmap for the green economy, outline the interdependences of the three dimensions of sustainable development and integrates them in a holistic perspective as advocated by UNEP, giving highlight to the role of business companies in obtaining solutions to common global challenges and establishing conditions.

ICC roadmap argues that collaboration between business companies and economic sectors is essential in order to make the transition to a green economy, proposing ten conditions as a framework for green growth on a set of interdependent policies and actions, as shown in Fig. 2.

The path to a greener economy is an ongoing process, but it has the potential to achieve sustainable development while reducing poverty on a

Green Economy II, Fig. 2 Green economy roadmap. (Source: adapted from ICC (2012))

high scale and velocity because it derives from a change in the social paradigm and a rethinking approach to the economy. Public policy, as a regulation, is important to provide direction through standards and targets, and public investments are crucial to enhance natural capital, new sectors, and technologies. In doing so public policies and investment will be the main source of growth and economic development when supported with additional investment in human capital, management, and technical skills.

Since it's a change of thinking and redefinition of the conventional methods of assessment of wealth, success, and well-being, moving toward a green economy will require a joint effort, a collaborative transition of world leaders, civil society, and leading businesses.

Summary

The green economy concept and operationalization have grown and developed in different

forms in different regions, depending on the strengths and weaknesses of each economy and of each nation, and it promotes a context of a safe and fair transition, in line with global challenges for sustainable development. State investments and policies are needed for the transition to a green economy which can have a role in decoupling economic growth from increasing current consumption of natural resources irrationally. The green economy is a complex but doable activity with enormous benefits, especially in the long term. In the actual context, economic growth is possible, but subject to certain conditions.

This perspective of growth and paradigm transition to sustain the transformation needed for the green economy make us expect a diffusion and convergence of environmental policy instruments, the emergence of green consciousness in national and international contexts, and the political strategy related to it. This ideal transformation is set, also, into the development of a socioeconomic model that builds on

service-based activities that don't demand material input and rely mainly on local activities and employment to foster social and ecological investments in infrastructures (Lederer et al. 2018).

This implies a policy change that doesn't regard the fact that similar structural drivers do not, necessarily, produce similar outcomes: the technological and economic factors do not make an effect automatically; they must be related to specific problems and turned into an appropriate solution (Lederer et al. 2018). However, if the change requires action and different actors, there is none stronger to enable and promote change than the state despite the state structures tend to favor the externalization of ecological costs, inhibiting environmental protection and merging with the deep-rooted mode of capitalist development.

Definition

Green Globe = 3S (safety, security, sustainability)

The Green Globe certifies hotels, resorts, conference centers, and other tourist attractions, ensuring that these tourism providers are the safest and the most secure in the world. It sets the highest standards in the field of sustainability.

Green Globe does not only provide a certificate but also offers training, education, and marketing services in a total of 83 countries around the world. The Green Globe Certification Standard is based on an internationally recognized set of criteria developed over 15 years by the Green Globe organization and awarded to companies with green solutions and a sustainable future.

The Green Globe initiative was launched in 1994 as a result of the UN Conference on Environment and Development in 1992. It is currently available in 83 countries around the world. To participate in the program, accommodations and other tourism providers must not only meet the specified set of requirements but also participate in Green Globe training, as well as seek the help of accredited consultants. The set of requirements includes systems developed for sustainability management, conscious management of social and economic impacts, protection of cultural heritage, and management of environmental impacts (Green Globe 2021).

Introduction

The Green Globe Certification primarily assesses the sustainability performance of tourism service

providers and their supply chain partners in a structured way. The standard includes 44 core criteria and more than 380 compliance indicators. The application of indicators depends on the type of certification, the geographical area, and other local factors. The standard is reviewed and updated annually.

The Green Globe 21 certification program was established in 1994 to prevent the tourism industry from being further regulated by governments. It is the only certificate in the world based on the principles of Agenda 21 sustainable development (Peřan 2008). It is supported by the Sustainable Tourism Cooperative Research Center.

The Green Globe Certification was established in 1998, which is an environmental certification for companies. The certificate does not entitle you to use the logo based on performance, but shows the commitment of the company. Green Globe has become an international environmental accreditation scheme, working with CRC Sustainable Tourism in Australia, forming an alliance with PATA Green Leaf, the Caribbean Alliance for Sustainable Tourism, and Green Key. These work platforms were operated in the following countries: the UK, Australia, South-East Asia, Caribbean, and Scandinavia. As a result of the expansion, Green Globe has become the largest network in the area, with international coverage as well as very little market penetration. The Asia-Pacific branch is the most active in this area, as through cooperation with the Tourism Industry Association of New Zealand (TIANZ), it is New Zealand's most aggressive eco-label, and it can make the most impact in this area. Since 2001, a complete package called "The Green Globe Path to Sustainable Travel and Tourism – As simple as ABC" has been prepared for sub-sectors of various industries, as well as training sessions in Australia and New Zealand (Font 2002).

The Green Globe (2021) also accepts locally developed standards, but basically builds on international standards:

- Global Sustainable Tourism Criteria
- Global Partnership for Sustainable Tourism Criteria (STC Partnership)

- Baseline Criteria of the Sustainable Tourism Certification Network of the Americas
- Agenda 21 and principles for Sustainable Development endorsed by 182 Governments at the United Nations Rio de Janeiro Earth Summit in 1992
- ISO 9001/14001/19011 (International Standard Organization)

In drawing up its audit program, which also requires an independent auditor, it relied on ISO 19011: 2002.

It is possible to obtain the Green Globe Certification in the following sub-sectors of tourism (Green Globe 2021):

- "Attraction
- Business (Whole Sale/Retail)
- Congress Center, Meeting Venues
- Cruise Ships (River & Ocean)
- Golf Course
- Hotel & Resort
- Meeting & Events
- Organization
- Restaurant
- Spa, Health Center
- Transportation (Mass Transportation, Bus Company, Limousine Service, Car Rental)
- Travel Industry (Tour Operators, Destination Management Company, Meeting & Incentive Industry)."

Certification Levels

Those who meet all the criteria will be granted Certified Member status. Businesses are inspected annually, and more than 50% of the indicators must be met to maintain status. The main topics are (Green Globe 2021):

- Sustainable management
- Social/economic
- Cultural heritage
- Environment

The Certified Member requires an independent audit every 2 years and a mandatory on-site audit

every 2 years. Gold Member status can be obtained by five service providers certified for five consecutive years and inspected in accordance with the regulations. Services certified for ten consecutive years can already be granted Platinum Member status, which is the highest level of certification (Green Globe 2021).

Advantages of Green Globe

Green Globe has the following benefits for tourism:

- 10% energy and water savings
- 7% staff safety improvements
- 7.5% consumer growth
- 1 million web audiences
- Media access per month

Companies can claim the following benefits with membership (Green Globe 2021):

- Because service providers use fewer resources and operate more efficiently, they can save money.
- Can connect and reach consumers who expect verified green credentials.
- Because they are constantly reviewing the operational process, they are better able to manage risks.
- Joining an industry-leading group means debt.
- Improve the brand image for companies by strengthening the green dimension.

Summary

Green Globe membership ensures that certified companies are successful in terms of sustainability for the company, the employees, the local community, and the environment, as they meet the following requirements (<https://greenglobe.com/about/>):

- They are committed to sustainability in management and operation.
- They are committed to reducing their use of energy and water and to reusing and recycling materials.

- They protect local culture and heritage.
- They have a sustainability plan, setting more than 300 targets that affect all levels of companies.
- They promote diversity and inclusion in the workforce.
- They act in accordance with local laws; promote equality, health, well-being, and human rights; and support global initiatives to prohibit the exploitation of children.

The importance and significance of the Green Globe International Standard for Sustainable Tourism is demonstrated by its two-decade history, the Global Sustainable Tourism Council also acknowledges it, and the Green Globe is an affiliate member of the UNWTO.

Definition/Description

Green jobs are defined as work in agriculture, industry, services, and administration that contributes to preserving or restoring the quality of the environment (UNEP 2008). They are considered to be a combination of traditional environmental science and engineering, combined with an orientation toward new regulations and a sustainability paradigm (Deitche 2010, p. xii).

The green jobs concept is part of a bigger trend in economics formally titled “green growth,” which refers to more environmentally sustainable production and distribution, as well as green finance. The public sector has been turning toward adopting policies that reflect the “green economy” paradigm as well (Deschenes 2015).

In terms of economic development, green jobs have been perceived as such jobs that have the dual

benefit of mitigating environmental challenges as well as helping green growth (Deschenes 2015). However, in terms of regarding green jobs, it has been a challenge to define which jobs exactly fit in this category. There is not a single list of criteria defining green jobs (Kouri and Clarke 2012). In the same time, more and more (both public and private) organizations acknowledge the importance of promoting a green job market development (Kouri and Clarke 2012).

Green jobs are present in both production and in the service sector. A special form of green jobs are the jobs in the renewable forms of energy sector (wind, hydropower, wind, geothermal energy, etc.). Another more specific form of green jobs has been considered the jobs that involve education, training, and raising public awareness – such careers turn to (Bronwyn Llewellyn 2008, p. 48).

Defining Green Jobs

The problem of defining green jobs is largely due to lack of formal international definition in either legal practice or in academia. For that reason a number of cognitive frames of perception of green jobs have emerged. A study from 2006 identifies five major frames in which green jobs are perceived:

- (i) Environment–economy bridge
- (ii) Green entrepreneurship
- (iii) Nascent industry creation
- (iv) Structural adjustment
- (v) Internal industry transformation (Kouri and Clarke 2012)

The academic treatments of the green jobs concept highlight the difficulties in defining the concept. However, despite having no clear border of the definition, the green job notion has been extensively developed as policy action by different countries.

Green Job Policies and Practices

Despite the lack of a universal categorization of the green job concept, most countries have implemented the green jobs notion in their economic policies and statistics. According to a 2012

report of the International Labor Organization (ILO), at least half of the global workforce (around 1.5 billion people) is engaged at least partially by the transition toward greener economies (ILO 2012). The ILO forecasts that more than eight million new jobs will be created globally.

In their efforts to advance the environmental economy sectors, countries invest in different projects and processes. Besides from the socially driven goal to protect the environment, environmental sustainability has been considered one of the promising fields for investing in research and development for achieving economic growth (Deschenes 2015). To stimulate green growth, investing in green technology and innovation is set as a priority by both developed and developing countries.

Green finance is regarded to play a role in environmental damage mitigation related to the impact of climate change on the economic system. Climate change poses new risks for the natural and economic systems, and finance toward the mitigation of these risks is stepping up. Green finance has begun to play more significant role as a facilitator of green growth (Noh 2019).

Governments have been stimulating enabling conditions for green transformation and green growth in different sectors – agriculture, buildings, energy finance, forestry, manufacturing, metallurgy and mining, transportation, waste and water management, etc. Measures to increase green growth and to create green jobs include stimulus packages, encouraging investment in sustainable business, financing research and development, etc. (Noh 2019).

However, governmental budget constraints ensure that green finance requires various market mechanisms for green growth investment. Private financing of green projects, however, is still associated with a high risk and low return of investments, for which reason the growing green finance sector relies on different investment tools (Noh 2019).

It has been a disputed topic whether tourism could be included as a target sector for green growth (Bronwyn Llewellyn 2008).

Box 1 Green Jobs in the Energy Sector

Renewable energy has been considered one of the core sectors of the green economy and green job market. Recent reports by the International Renewable Energy Agency (IRENA) state that in 2019 more than 11.5 million people were employed in the renewable energy sector globally. The highest number of estimated direct and indirect jobs in renewable energy is in China, with the country having more than 4,000,000 people employed in the sector. India, Brazil, the EU, and the USA are among the other global leaders in number of green energy jobs (IRENA 2020).

Green Jobs and the Labor Market

Despite that the scope of green jobs can vary, it has been estimated that the role of such workplaces is rising in the labor markets (Fig. 1).

A rise in demand for high-skilled professionals has created a hard-to-fill gap in some green job markets. A significant difference between low-skilled and high-skilled labor supply repeatedly raises the questions about the role of education and training in securing the required labor force for the green economy. The main issue in education related to green jobs has two dimensions.

On the one hand, an inability of education and training systems to respond to the demands of the growing green industry is defined as a problem (Maclean et al. 2018). Universities and training centers have been working together with businesses and industries in the sector to resolve this problem. More and more do business-university partnerships address this issue by creating joint programs and practical trainings.

The other barrier that education has in the sphere of high-skilled green labor force training meets is related to the prospective students' preferences. A shortage of prospective students choosing to specialize in green skills in demand,

as well as structural problems such as lack of employer incentives to invest into transferable skills training and the existence of stereotypes are additional such obstacles to achieving the optimal number of students training for the high-skilled green jobs segment (Maclean et al. 2018).

In order to overcome the shortage in green jobs supply, the United Nations Environment Program (UNEP) and the International Labor Organization (ILO), in cooperation with the International Trade Union Confederation (ITUC) and the International Employers Organization (IEO), launched the UN Green Jobs Initiative in 2008 (UNEP 2008; ILO 2019).

and practical aspects confirms the tendency toward economic transformation than more sustainable economies and green growth.

Due to the development of instruments for green growth funding, the green jobs labor market has witnessed a considerable rise in the last decade. However, there are still some structural challenges that the green job market has, which concern the demand for highly skilled labor. Through associating education with the green growth notion, new programs and showcasing of the benefits of green professions have been launched by educational institutions in order to attract more people into these spheres of professional training.

Summary

Green jobs are an essential factor for sustainable development. The understanding that an environmentally sustainable economy has to be created with thought of economic development is addressed by creating new job markets in green jobs, training professionals, and investing in green technology.

Green jobs are an essential part of the green growth economic paradigm. The rapid development of the green jobs sector in both conceptional

Green Jobs Social Life Cycle Assessment

Muhammad Farooq
Yasar University, Izmir, Turkey

Synonyms

Circuition; Communal; Community based; Environmental jobs

Definition

The global environmental awareness has given rise to many terms that were not emergent before. In particular, the terms related to sustainability are of keen interest. More businesses and societies as a whole are trying to shift the focus more towards the green terms, sustain bile solutions, and effect resources use. In this regard, green jobs and the social life cycle assessment of them are an emerging concept.

Green jobs creation is the concept that emphasises on value creating activities, focusing on environmental protection to uplift the conditions of economic and employment generation for local areas (Zimmermann and Simpson 2013). Moreover, two other variables having an impact on green job creation are effectiveness of managerial and public policies which enhance the green job creation activities (Mintzberg 1973).

Green jobs are a broad concept which is conceptualized as an employment in clean energy sectors or environmentally conscious conditions. There is no globally accepted definition of what constitutes a green job. Mostly the definitions that statistical agencies and researchers use term them as employment in clean energy or the production of environmentally friendly goods and services. While few researchers define green jobs precisely as the jobs which emerge as a result of green growth policies, in this regard, the United Nations Environmental Program (UNEP), which sets some criteria for a job to be called a green job, mentions that it must offer adequate wages and support workers' rights and sufficient safety conditions at workplace.

It is pertinent to mention the Green Goods and Services Survey (GGS) from the USA. It considered two definitions for the green jobs concept:

They present output-based and process-based definitions.

1. “Jobs in businesses that produce goods and provide services that benefit the environment or conserve natural resources.”
2. “Jobs in which workers’ duties involve making their establishment’s production processes more environmentally friendly or use fewer natural resources” (Deschenes 2013).

Similar definitions have been accepted in other countries too, naming Germany and France where a single definition does not exist, but major focus is given on environmental and clean energy-related fields. The definition in Germany points to “employees who produce environmental goods and services, or employees involved in environment-related activities.”

As the sustainability related concerns rose specially after Burtland report (1987), the concern about including the social and economic factors into the life cycle of a product. The discussion about inclusion of socio-economic factors in the life cycle of goods started in 1990s, with the publication of The Society of Environmental Toxicology and Chemistry (SETAC) Workshop Report: “A Conceptual Framework for Life Cycle Impact Assessment” (Fava et al. 1993). In the year 2004, United Nations Environment Programme (UNEP)/SETAC life cycle initiative acknowledge a need for inclusion of social criteria into LCA. The term from LCA transcended to S-LCA, defined as a systematic process of utilization of the optimal available science to congregate optimal available data to report on the social impacts, negative or positive, in a life cycle of a product from initiation to disposal. SLCA are used to inform the management, or a concerning body, about the social impact by communicating, identifying, and reporting impacts, which further helps to formulate policies and strategies (Benoît et al. 2010).

Introduction

Green concept, primarily as mentioned by Kenneth Odera (1850–1928), surfaced in the Garden City Movement, by Sir Ebenezer Howard that showed the issues of a green economy for localities and cities (Zimmermann and Simpson 2013). The green jobs’ definitions mainly focus on energy from renewable sources and their efficiency, reduction in pollution, addressing the green house gases, recycling, public awareness, and trainings. United Nations Environment Programme (UNEP) in 2007 with the International Labour Organization (ILO) discussed the concept of Green Jobs to promote the economic and

environmental growth and urge governments for green investments. The aim was more job creation and to change the social life cycle of existing jobs into more sustainable practices.

Green jobs in the initiation phase of their social life cycle require high investments in establishing newer innovative technologies and methods of production, training the human resource. They are also developed special zones for investments, in green jobs, like Silicon Valley, namely, and East Asian Countries, which also can create inequalities globally not having the equal universal opportunities, and specially the exclusion of female workforce. Furthermore, the technological changes that appear as a result of moving towards greener jobs are also dynamic. Moving into newer technologies, policy shifts also alter the social life cycle substantially. Newer training needs, and technology adoption might not be uniformed and evenly distributed in all regions (Mulvaney 2014).

Frameworks for Green Jobs Social Life Cycle

Understanding the green jobs social life cycle is complemented by development of frameworks by researchers. Frameworks established by researchers have been studied by Sureau et al. (2018) that have pointed out different characteristics of green jobs social life cycle.

Value-Based Frameworks

Different researchers are divided into value-based frameworks which can be used in the context of green jobs’ social life cycle.

Benoît and Mazijn (2009) purpose several options to reduce risks and chalk out procedures for purchasing, reporting, marketing, planning, and development of public policies. They focused on social and socio-economic impacts of processes throughout their life cycle. They assessed impact of jobs on stakeholders.

Dreyer et al. (2005) in the same value-based domain worked at the decision making. Green jobs involve decision making at critical moments where you have to make choices in shifting the company policies towards greener practices other

than the usual operations. They also researched on the impacts of jobs on the stakeholders in detail and worked in the field of practices in jobs that are related to workers, their performance, and how are they treated. Green jobs consider the treatment of workers fairly as one of the prime factors, and the social life cycle throughout the job revolves around it.

Kruse et al. (2008) discussed the social impacts of the choices made by policy makers and customers' practices and compare different jobs for the same products. They primarily discussed production-related green jobs.

Context-Oriented Frameworks

Wangel (2014) focused on Nussbaum capabilities and results from SLCA models to make new chains and the contexts that enable value delivered to stakeholders. He sees the impact and effects of green jobs on stakeholders.

Mathe (2014) discussed the impacts of industry on the ecosystem and the matching of the principals and their impacts on the environment.

Theory-Structured Frameworks

Reitingering et al. (2011) focused on performing comparative analysis on industries to find the optimal process within the industry, sector, or organizations. The social life cycle of green jobs depended on the degrees of freedom and working of the stakeholders.

Garrabé and Feschet (2013) argued at increasing the modification in green jobs to increase the social and economic impact by modernization and improved decision making process that leads to newer activities, better productivity, and change in location and increased lifecycles for green job ensuring better economic and social outputs.

Macombe (2013) and Gaasbeek and Meijer (2013) focus on the role of decision making in social life cycle, the commencement of technology, and the cause effect relationship and how they impact green jobs.

Applicability-Oriented Frameworks

In these frameworks, the researchers focused on the applicability of different standards and practices on green jobs throughout the social life cycle.

Labuschagne et al. (2005) discuss the management purposes, social sustainability impacts of new technologies, engineering, and processes. The impacts on the local communities due to the process adopted by companies in their green job formations.

Fontes (2014) worked on social metrics side of social life cycle for green jobs. He aimed to highlight the areas for improvements, assistance in decision making, and communication throughout the lifecycle. He assessed the performance in green jobs in its impact on local communities and society.

Summary

The green jobs have been embraced by the authorises and a step towards realizing the dream of sustainable environments. The social life cycle of green jobs is complex as their impact on societies is taken differently, and more regulations, rules, laws, and customs are applied on green jobs than regular jobs. From inception to disposal, every stage in green jobs is observed to see how social and economic are being impacted. Where the green jobs are considered to be the custodian of sustainability practices, it is also in the initiation stage that requires more investments. The social impacts on the society are a win-win situation for both society and economically as the economic activity generation helps the society and environment too and lesser harmful impacts are transmitted on them.

Definition

Green Marketing is a set of marketing strategies and activities defined and created to facilitate transactions of goods and/or services with the goal of satisfying the needs and desires of environmentally sustainable consumer concerns. Consequently, the way products and/or services are produced, commercialized, distributed, and detached must respect the environmental and sustainability concerns of the consumers and must be clearly and reliably stated and demonstrated.

Introduction

Due to a growing group of consumers that are more and more concerned with the environmental preservation and protection, facing this new environmental paradigm, companies have reorganized themselves and defined new strategies to ease new positions on markets, with marketing being given great responsibility in their design and implementation and, therefore, positioning themselves as more socially responsible in terms of products, operations, and performance.

The purpose of marketing, in the context of the demand for sustainability, is to achieve optimal satisfaction of consumer desires, allowing the use of environmental functions in the form of products or services, without exceeding the external limits determined in the search for this sustainability (Van Dam and Apeldoorn 1996). Sustainable marketing should help to find defensible exchanges between business and environmental concerns. It takes on, among other things, an attraction for increasing business horizons and continuing value on profit. Through proactive marketing, which measures consumers' needs and expectations and offers the market the appropriate choices to meet their needs, it is possible to achieve sustainability (Sheth and Parvatiyar 1997). The allegation that marketing serves social needs by informing consumers of the availability of goods and services in order to improve their quality of life can only be supported if the perspective of communication and its techniques are informative. This implies that marketing has an educational function, channeling the needs of current and potential consumers to products, services, or ecological activities (Sheth and Parvatiyar 1997). Implicit to this statement is the assumption that marketing efforts are also aimed at reforming inefficient and environmentally friendly consumption habits: "Changing consumption patterns can involve positive incentives, new products and development of processes and prices against certain consumer practices" (Sheth and Parvatiyar 1997: 7).

The ability of marketing to identify and develop consumer choices for society and meet your current needs without harming the ability to meet your

future needs allows you to develop "green" products in a way that improve poor environmental conditions. As such, the concept of "green" product assumes that environmental consequences are the most important determinants of its acceptability rather than the satisfaction of the company or the profit of the company. The truly "green" product is the one that becomes the consumer's first choice as long as it meets the individual's consumer needs alongside their needs of a healthy and sustainable physical environment (Sheth and Parvatiyar 1997). These two types of needs are not conflicted; both occur simultaneously.

Bearing in mind the concept of "green" product, marketing managers found that environmental themes usually provide a source of competitive advantage (Schultz II and Holbrook 1999). Therefore, companies focus on the problem of sustained growth or development (Elkington 1994; Hart 1997; Ruckelshaus 1989) while managers aspire to the Ecological (Fisk 1974), Environmental (Polonsky and Mintu-Wimsatt 1995), Green (Ottman 1997; Wasik 1996), and more recently to Enviropreneurial (Kilbourne 1995; Hartman and Stafford 1998; Menon and Menon 1997; Kangun et al. 1991) products.

From Ecological to Enviropreneurial Marketing

The marketing process of incorporating the environmental concern into its concept, strategies, and operations suffered a transformation during several years, focusing on different perspectives, as shown in Fig. 1, before green marketing gaining common usage, as it is used today, namely ecological; environmental; green; and enviropreneurial.

The first framework developed to integrate environmental concerns into marketing, the Ecological Marketing concept as Kotler's (1986) called it, has a social marketing base that states that the main goal of business is to identify market needs, desires, and interests and develop products targeted to satisfy the consumers in a more effective and efficient way than its competitors, preserving at the same time the consumer's and society well-being

Green Marketing, Fig. 1 – Incorporation of the environmental concerns within the marketing concept (Adapted from Paiva and Proença 2011).

(Wasik 1996). This social marketing concept has the main idea underlined that marketing is part of a holistic management perspective (Xue et al. 2018). The products are evaluated on how they are produced, packaged, transported, consumed, and dispensed (Wasik 1996).

The Ecological Marketing concept (Henion and Kinnear 1976; Fisk 1974) emphasize business managers recognition of the ecological crisis, which leads to business taking responsibility and alter their management practices and work to avoid this crisis (Gordon et al. 2011; Hunt 2011; Van Dam and Apeldoorn 1996). However, having environmentally friendly products was not sufficient to have market success since the consumers and supporters of environmental protection and preservation weren't enough to stimulate properly the demand and therefore have a business that is rather valuable (Van Dam and Apeldoorn 1996). At this time, most of the consumers weren't predisposed to change their behavior and adopted collectively more environmental preservation and protection actions.

The Environmental Marketing viewpoint arouse into the market by trying to influence consumers that they could achieve higher levels of satisfaction by buying fewer products. In doing so, it was not expected to just recognize environmental problems to make behavioral changes but also to change the social paradigm, leading to buying less. This perspective translated the social need of production with less waste and lower consumption into market-oriented management (Gordon et al. 2011; Hunt 2011; Van Dam and Apeldoorn 1996) supported by business costs reductions and governmental legislation. Yet, changing social paradigms is not easy task and takes time; the consumption in large quantities and/or variety, i.e., the hyper consumption of modern Western society has proven to be a strong opposition to this perspective. The psychological role of possession and materialistic consumption was taken too lightly by both Ecological and Environmental marketing (Van Dam and Apeldoorn 1996).

The process of integration for the environmental concerns into the marketing concept evolved and the Green Marketing perspective arouse as a

result of the business need to answer to the growing market demand of "environmentally friendly" products. Therefore, the moral and social motives underlined in the previous perspectives were replaced by market pressures and competitive needs (Van Dam and Apeldoorn 1996). These three perspectives are the combination between the need to reach profit and the sustainability of the environment quality (Gordon et al. 2011; Hunt 2011; Van Dam and Apeldoorn 1996).

The Green Marketing focuses on the market and the legislative push to promote a "friendly" business performance of the environment and is seen as an interaction process between the consumers' sensitivity to the environment, the competitive intensity and the legislative intensity (external political and economic strengths), and the environmental awareness of managers, i.e., the increased sensitivity of entrepreneurs to the environment within the business (Langerak et al. 1998). The success of green marketing is reflected in the responses of consumers and the financial performance of the business. The implications of the performance of green marketing are fundamentally based on the ability of the business to collect premium prices on green products, reduce costs through environmental programs, and perform to produce high results (Ottman 1997; Wasik 1996). The business appealing for environmental issues grew but the macroaspect of the subjects was ignored since the concept of sustainability in the marketing framework does not only imply adding a new element of competitiveness, it is also not enough to analyze the extent to which the "green" companies can be profitable and act accordingly (Gordon et al. 2011; Hunt 2011; Van Dam and Apeldoorn 1996).

However with the success of Green Marketing point of view and the growing number of products and services introduced into the market, some problems were identified (Menon and Menon 1997) that could only be solved if the integration of the environmental concerns were translated into the a single Enviropreneurial Marketing strategy.

The Enviropreneurial Marketing perspective is the result of the definition and implementation process of marketing activities beneficial to the

business and to the environment since the main goal is to create returns through the exchanges that will satisfy the business aims in economic and social terms (Menon and Menon 1997). This perspective considers that environmental degradation is the result of the interaction of human experience, technological growth, and economic development. Thus, these same forces must be at the root of the solution for environmental problems and not the legal pressure, the laws of command and control, and the increased regulation of activities; so, ecological and innovation technologies are proposed as strategic options to develop competitive advantages and solve environmental problems (Wong et al. 2015; Shrivastava 1995). Enviropreneurial Marketing is therefore different from the previous as it adopts a solution of innovation and technology (new forms of production, packaging, and distribution and new forms of destruction or recycling of waste in the production or consumption) rather than a public and legal pressure solution and it represents the confluence of social performance and environmental and economic goals (Menon and Menon 1997). As some authors stated (e.g., Stopford and Baden-Fuller 1994; Coddington 1993; Hunt and Auster 1990, referred to by Menon and Menon 1997), this point of view is a business philosophy as one of the core values that guide this strategic marketing perspective is the view that the imperatives of the environment can be market opportunities rather than business constraints. So, this perspective has a social marketing performance, intrinsic to its nature and objectives of the strategies and tactics (Menon and Menon 1997).

In many business cases this last perspective offers an accomplishment of social responsibility concern. So, to them, now, when put to practice their environmental concerns already underpin an environmental philosophy (Paiva and Proença 2011). This transpires not only a climate of credibility, but also allows business to focus on strategic and operational actions that are market oriented, from an essentially green point of view. For this reason, it is allowed to call Green Marketing to the integration, in marketing, of the environmental sustainability of business companies.

Green Marketing

The Green Marketing concept, as discussed before, express the demand of environmental sustainability in business and it is transferred into business, within its business strategy, in a holistic perspective (throughout its goal definition until the more operational details to be implemented). Nowadays, not only society has changed into a more sustainable paradigm but also business are addressing the market in a new perspective since consumers are seen as human beings looking to have a full and healthy lives, where their values and sensitiveness are projected in the materials goods they acquire and the lifestyle they live (Ottman 2017). An ecologically and socially responsible business associates environmental stakeholders in cooperative alliances and works with suppliers, retailers, and local governments (Yu et al. 2017; Wong et al. 2015) to manage environmental and social issues throughout their products value chain to seek profit and business contribution for society and the planet, as shown in Table 1.

Green Marketing, Table 1 – The new green marketing paradigm

	Conventional marketing	Green marketing
Consumers	Consumers with lifestyles	People with lives
Products	“Cradle to grave” Globally sourced One size fits all	“Cradle to cradle” Locally sourced Regionally tailored
Marketing	Products–end benefits Selling One-way communication Paid advertising	Values Educating and empowering Creating community Word of mouth
Corporate	Secretive Reactive Independent and autonomous Competitive Departmentalized Short-term oriented/profit maximizing	Transparent Proactive Interdependent/ allied with stakeholders Cooperative Holistic Long-term oriented/triple goals (profit, environment, and social contribution)

Source: Adapted from Ottman 2017

The new paradigm of the green marketing concept, as observed in Table 1, implies a more transparent and proactive and cooperative firm that answers to the consumers' needs in a more holistic approach in which the business companies have different strategies to response to the market challenges.

Summary

The environmental and sustainable consumers concern in integration into business management, in its constant seek of needs and human concerns and overall society adaptation, had different perspectives over time. Consequently, marketing was named in different ways until the denomination of "Green Marketing" became more widely used due to its simplicity in aggregating several sustainable environmental questions and concerns, in the consumers' and business perspective. Today, the Green Marketing concept integrates a holistic perspective, questioning the different entrepreneurial activities in an environmental and sustainable context. This concept is based on the ecological marketing moral and ethical vision, in a market perspective, using marketing tools, legislation, and social pressures of various stakeholders to promote an entrepreneurial and environmental performance seeking the balance between consumer's sensitivity to the environment, competitive and legal intensity, and the conscious and environmental sensitivity of the managers and entrepreneurs.

There are different strategic options, and operational guidelines, to define a Green Marketing route in this meeting of social performance and environmental and economic goals.

This becomes more urgent since the consequences of environmental destruction are already being felt. It is critical to promote this marketing perspective and help business to offer a sustainable answer to society's needs, becoming agents of positive social and environmental "zero" impact.

Green Rewards

Ewa Beck-Krala
Faculty of Management, AGH University of
Science and Technology, Krakow, Poland

Synonyms

Green compensation; Green pay; Pro-ecological rewards

Definition

Green rewards systems are rewards policies, programs, procedures, and tools designed to preserve and protect the environment through increasing pro-ecological employee awareness, attitudes, and behaviors. As one of the CSR rules is “do no harm,” green rewards programs are primarily aimed at reducing the negative environmental impact (footprint) of the organization and its employees (Beck-Krala and Klimkiewicz 2018). These programs are designed to create and strengthen attitudes and behaviors that support pro-ecological activities.

Introduction

Rapid environmental changes and catastrophes caused by irresponsible and devastating human activities have drawn our attention to the need to preserve the natural environment. It is obvious that only an integrated effort and comprehensive action taken on all three levels: individual, organizational, and societal can bring about the desired results. Increased awareness of the necessity for such action by many employers has resulted in the implementation of many programs and initiatives which constitute new approaches in management. These have been labeled *green management*, *pro-ecological management*, or *environmental management* (Ahmad 2015). This comprehensive approach toward green management focuses on increasing awareness and promoting desirable behaviors (see Jackson et al. 2011) of the organization’s most important stakeholders (employees, managers, clients, etc.). Most actions, however, are directed toward internal stakeholders – employees. In fact, both the literature and practice have shown an increase in organizational sustainable development activities through the introduction of appropriate practices and tools in human resources management (HRM) (Renwick et al. 2012). This approach is called Green Human Resources Management (GHRM) (Jabbour 2011; Renwick et al. 2012). GHRM practices include recruitment and selection, training, performance management, rewards systems, and

involvement (Jackson et al. 2011; Renwick et al. 2012).

According to the Chartered Institute of Personnel and Development study (CIPD), HR professionals believe they should actively support the organization in pro-ecological activities (Renwick et al. 2012, p. 36). Rewards may play an important role in engaging employees in pro-ecological initiatives and promoting environmentally friendly employee attitudes and behaviors. Embedding green practices in HR, particularly in rewards, can reduce the company's environmental footprint and enhance the likelihood of a company's sustainability (Renwick et al. 2012; Yong et al. 2019). This new direction in green management – *green rewards* – is gaining more and more attention in practice, but few publications have explored this issue (Beck-Krala and Klimkiewicz 2018).

The Idea and Context of Green Rewards

Green rewards are a part of green HRM that is designed to build employee identification with the organization's environmental goals. Green rewards systems are rewards policies, programs, procedures, and tools that are aimed toward preserving and protecting the environment through increased pro-ecological employee awareness, attitudes, and behaviors. As one of the CSR rules is “do no harm,” green rewards programs are primarily aimed at reducing the negative impact (footprint) of the organization and its employees on the environment (Beck-Krala and Klimkiewicz 2018). Green pay and rewards systems consider financial and nonfinancial rewards for organizational members whose attitudes or behaviors are conducive to environmental management (Jabbour 2011). In fact, most companies that present a comprehensive approach toward green rewards integrate both financial and nonfinancial formal and informal rewards programs that are linked to green and responsible employee behaviors. A comprehensive, clear, and consistent green rewards approach integrates programs and procedures from the total rewards package. Examples include programs aimed at reducing pollution,

reducing water and energy consumption in the workplace, and volunteering programs that recognize pro-ecological initiatives directed toward protecting the local environment, such as cleaning the local forest or river or planting trees, where the best team or individual is recognized for these efforts but not necessarily compensated financially.

Green rewards are also closely connected with *green performance management* (GPM), another aspect of GHRM. Employers can appraise employee behaviors and the environmental results of these behaviors to assess their contribution to organizational pro-ecological goals. Employees may be evaluated on green criteria. Green performance is measured according to environmental measures and may also be a basis for accrued bonuses, rewards, or pay raise. Green performance indicators may be connected with environmental incidents, environmental responsibilities, reduction of carbon emissions, communication of environmental concerns, etc. Both green rewards and green performance are directed toward environmentally positive employee behaviors within the organizational context. Such programs may also influence employee behavior in their private lives. Another important *green* topic in the literature is called *green work-life balance* (Muster and Schrader 2011). Employees who fulfill their workplace responsibilities are also consumers in private life. This view considers employee behaviors and attitudes both at work and outside work. This balance means that organizations offer incentive programs that support pro-ecological behaviors at work as well as educating and increasing employee awareness so they can effectively reduce their negative environmental footprint.

Classification and Examples of Pro-environmental Employee Rewards Programs

Green human resources practices, such as green rewards, may strengthen the motivation and involvement of employees in shaping the green organizational culture and introducing environmental innovations or even reducing the negative

impact (e.g., controlling the indicators) on the environment. Depending on the organizational strategy and main goals, various programs are offered. These programs are also diversified, depending on the sector, industry, type of influence that the organization has on its environment, and the role of the employee within the organization (Klimkiewicz 2017). One classification that concerns the goals of green rewards programs was offered by Jackson et al. (2011), who identified:

- Incentive programs that reward the pro-ecological behavior of employees
- Incentive programs for eco-innovations
- Programs that educate and support pro-ecological activities in private life

Rewards play an integral role in initiating environmentally friendly activities involving employees as a part of green initiatives and also initiating changes and innovations in existing processes.

According to other *general classifications*, green rewards programs may be divided into financial, nonfinancial, individual and team-oriented, formal and informal, and addressed to managers and employees, as well as targeted at internal and external stakeholders (Beck-Krala and Klimkiewicz 2018).

Financial green rewards programs include increases, bonuses, and prizes dependent on the attainment of environmental criteria and objectives and reducing the organization's negative environmental impact. Such programs may be linked to the organization's strategic objectives or result directly from the organization's CSR strategy. These programs are usually targeted at employees and managers at all levels. A look at the popularity of green financial rewards programs reveals an increase in linking managerial compensation with pro-environmental goals – up from 15% in 2012 to 24% in 2014 (McCullough 2014).

Nonfinancial green rewards programs have a tremendous potential for motivating employees (Renwick et al. 2012). Due to the range of the impact of these programs and the various groups

of stakeholders they address, they can also be divided into those targeted toward internal stakeholders (supporting ecological actions on the job and in the workplace) and those motivating employees to take action for external stakeholders (supporting ecological actions outside the workplace). Within the organization, most financial programs link bonuses or increases to the realization of ecological goals closely connected with organizational activity, for example, reducing the amount of resources used for production or work. Most nonfinancial programs, on the other hand, are directed outside the organization, as they can realize, for example, important purposes for the local community. Giving employees the opportunity to realize pro-ecological projects during work time can be viewed as financing the work-time pool dedicated for this purpose (Renwick et al. 2012). Employees have the opportunity to realize their own ecological ideas and develop competence based on the organization's infrastructure. This benefit can be considered as part of a balanced incentive system (Jackson et al. 2011). Nonfinancial recognition programs reward employees for pro-ecological activities with material prizes, such as paid extra free time, public praise, certificates and trophies, or ceremonial galas and dinners (Table 1).

Some examples of various incentive programs aimed at increasing awareness of environmental protection and involving employees in pro-ecological activities include the following:

- Intel Corporation (IT), where each employee's compensation is linked to ecological criteria
- Alcoa (aluminum company), where employees earn a bonus based on green carbon reduction targets and improving safety at work (McCullough 2014)
- Chevron's energy group and GlaxoSmithKline (pharmaceutical company), where employee compensation is bound to reduced use of resources and reduced environmental impact, enabling financial savings, improved work processes, and reduced resource consumption (Brammer et al. 2015).
- Eco-innovation group programs at Xerox (Earth Awards)

Green Rewards, Table 1 Financial and nonfinancial green rewards programs

Green financial rewards (pay and incentives)
Pay increases dependent on achieved environmental goals
Individual and team incentives based on ecological criteria, such as ecology innovation programs, giving environmental benefits to employees, such as water and electricity use reduction programs in the workplace, greater use of recycling, and reuse of paper in the workplace
Individual and team financial bonuses for actions taken and achievements in the field of environmental protection
Financial awards for employee suggestions and solutions that significantly reduce the organization's negative impact on the environment (eco-innovations)
Incentive programs rewarding development of employee competencies in the field of environmental protection, e.g., knowledge of environmental legislation in the industry
Long-term incentives that link executive compensation with achievement of environmental goals
Green nonfinancial rewards
Additional benefits offered to employees in order to protect the environment, called green benefits, which can be related, for example, with transport (green travel)
Benefits that support socially responsible behavior and environmental attitudes not directly related to environmental protection
Nonfinancial employee recognition programs for environmental initiatives
Time frame for pro-environmental action/ecological projects. The paid-for-work time, when employees voluntarily engage in such activities is geared toward increasing employee motivation and engagement. Projects implemented in this way may be imposed by leaders or be employee initiatives.

Source: Based on Renwick et al. 2012; Beck-Krala and Klimkiewicz 2018

- Dow Chemical and ICI Americas, where employee green suggestions and exceptional achievements in this area result in incentive and bonus programs (Arulrajah et al. 2015).

Employers may also offer green travel which includes rewards aimed at reducing the carbon footprint and promoting a greater awareness of environmental protection for travel and employee transport. Green tax exemptions promote the use of transport that is less harmful to the environment – bicycles, electric scooters, and electric cars. Finally, green recognition includes nonfinancial rewards programs for employees, such as company-wide public recognition, paid vacations, or gift certificates. Nonfinancial rewards lead to pride and internal satisfaction and more effectively encourage eco-initiatives.

Benefits

Green rewards programs support the organization's strategic goals in this area and enable the branding of the employer as responsible, an important consideration for younger employees

when choosing a place to work. Thus, green rewards build the company's image and help to obtain financial benefits (Report: Business and Ecology, 2011). Studies have shown that the long-term performance of companies linked to financial rewards leads to a reduction in environmental pollution, giving a greater scope for prevention of pollution (Berrone and Gomez-Mejia 2009). Research also shows that green rewards improve employee relations and shape their attitudes and awareness of environmental protection. In turn, motivation and engagement are listed among the benefits of company green initiatives (Report: Business and Ecology, 2011), which show that changing attitudes of employees and increasing their involvement may be an unintended consequence of pro-environmental policies.

One of the greatest benefits of providing eco-friendly rewards programs is building employee engagement. Integration of the interests of many stakeholders is the basis for high employee engagement (Beer and Eisenstat 2009). The socially responsible employer's actions in the area of environmental protection support the sense of material safety of employees and safety

in the workplace (e.g., healthy working conditions, secure pay at a decent level). Studies conducted in Denmark show that incentive programs that combine employee participation and environmental advocacy within organizations are extremely effective. The introduction of financial bonuses has increased participation of employees in green initiatives when they were given the opportunity to perform such activities during their work time (Forman and Joergensen 2001).

Benefits obtained in the psychological dimension can also be significant. The literature points to promoting employee self-confidence and respect for diversity in the workplace and building a sense of belonging to a group where values are respected. As a consequence, the number of counterproductive employee behaviors is often diminished, as these are often a result of the lack of loyalty to the employer and co-workers. Environmental and local community action gives employees a sense of authenticity and sense of work (Bauman and Skitka 2012). In turn, CSR activities positively influencing the image of the employer also give a sense of pride to the employee for working for a socially responsible company.

Summary

The system of employee rewards is an important factor in Green Human Resources Management. Although the literature addressing this issue is rather scarce, it does contain some tips for shaping rewards programs that support responsible and environmentally friendly behavior. Green rewards systems are rewards policies, programs, procedures, and tools that are aimed toward preserving and protecting the environment through increasing pro-ecological employee awareness, attitudes, and behaviors. As one of the CSR rules is “do no harm,” green rewards programs are primarily aimed at reducing the negative impact (footprint) of the organization and its employees on the environment. A comprehensive, green rewards approach shows the consistent integration of many programs and procedures from the total rewards package and results from a clear,

sustainable CSR policy that does not just focus on one initiative. In practice, there are various types of green rewards programs.

It has been argued that employees may feel more motivated by nonfinancial rewards through green rewards, such as recognition and praise (Jabbour 2011; Jackson et al. 2011); however, the integration of both types of rewards seems to work the best.

Definition

Green Taxation, also known as Environmental Taxation, involves the use of taxation to promote more responsible environmentally taxpayers' behavior, through tax penalties, in order to punish the polluting behavior, or tax benefits to encourage good behaviors. Definitions of this concept can also be found outside the scientific context, for instance, according to the Carbon Brief Staff (2013) this concept "...is commonly used to refer to a package of government measures intended to encourage expansion of low-carbon power, subsidise home insulation and tackle fuel poverty." Additionally, the United Kingdom Government (2012) states that "Environmental taxes are defined as those which meet all of the following three principles: (i) the tax is explicitly linked to the government's environmental objectives; (ii) the primary objective of the tax is to encourage environmentally positive behaviour change; (iii) the tax is structured in relation to environmental objectives, for example: the more polluting the behaviour, the greater the tax levied."

Moreover, the concept of green taxation is inextricably linked with the concept of Green Tax Reform. This type of tax reform seeks to introduce environmental taxes, thereby replacing much of the traditional taxation on companies (income and capital), labor income, and contributions to social security systems, in order to reduce unemployment levels (Álvarez et al. 1998; Alves

and Palma 2004). Thus, the Green Tax Reforms presuppose the obtaining of a double gain, denominated by effect of the “double dividend”: the environmental gain and the reduction of unemployment, by tax relief on labor.

Introduction

The idea of taxing pollution is not new, its first reference is associated with the British economist Arthur Cecil Pigou, in 1920, that is why the green taxation is also known as Pigouvian Taxes (Sandmo 2003).

The “polluter-pays principle” is a generally accepted basic principle of environmental law, which was partly based on that old idea of taxing pollution. This principle has two different currents concerning to its application form: on the one hand, those who defend its direct application, in particular through greenhouse gas emission quotas; on the other hand, those who support the indirect payment, mainly through environmental taxes that penalize polluting behavior.

In this scope, since the 1990s, most studies on Green Taxation intend to ascertain the best way to apply the “polluter-pays principle”: the direct application or the use of Green Taxation. Thus, several authors developed studies, mainly based on mathematical models of general equilibrium, where they conclude that the application of Green Taxation results in better environmental results than the use of direct environmental tools, such as greenhouse gas emission quotas (Baranzini et al. 2000; Goulder et al. 1999; Hong 2015; Sandmo 2003).

The importance of taxation as an environmental “tool” was recognized in the academic context but also by several organizations with key roles in the international environmental context, such as the EU (European Union) and the OECD (Organization for Economic Cooperation and Development), in consequence, it has been extended to a great number of countries.

Despite the widespread use of Green Taxation by countries not belonging to the European Community, in fact it is based on a reform advocated in the European Union in 1993. Thus, the European

Union’s “White Paper on growth, competitiveness and employment,” known, as already referred to, as Green Tax Reform, relies on the following assumptions: (i) introduction of green taxes that substitute the traditional forms of taxation; (ii) integrated economic and environmental objectives; (iii) use of taxation as an environmental “tool”; (iv) obtaining of a double positive effect, referred to in the literature as the “double dividend,” that is, to obtain, also, economic gains, for instance, by reducing unemployment, through social security contributions reduction (Álvarez et al. 1998; Borrego 2016; Bovenberg and Mooij 1995).

In relation to the “double dividend” effect: the “first dividend,” that is, the environmental gain, is consensual in the previous literature; however, the “second dividend” is a controversial issue in academia.

In relation to the authors who defend the existence of a second positive gain, there are two lines of research around the type of gain, with, on one hand, the European authors defending that the second dividend is the decrease in the levels of unemployment and, on the other hand, the North American authors defending that the second dividend are the gains of efficiency and competitiveness of the economy (Bovenberg and Mooij 1995; Lee and Misiolek 1986; Terkla 1984).

There are also some authors who question the existence of a positive impact on employment, or on the economy, provoked by the introduction of green taxation: some of them conclude that this “second dividend” does not exist, others verify that the second impact exists, however, it is negative, that is, the Green Taxation has a negative impact on employment or on economy, mainly because that type of taxation affects the consumption.

Despite this controversy over the “second dividend,” some studies have gone further and point to the existence, in some countries, of a “third dividend”. Thus, in recent years, in studies on developing countries, as well as in some countries with major problems of budgetary stability, has been identified another gain: “the reduction of poverty” or “the budgetary balance” (Heerden et al. 2006; Pereira and Pereira 2014).

The analysis, classification, and evolution of green taxation have also been the subject of studies in some countries (Álvarez et al. 1998; Barde and Owens 1996; Borrego 2016; Carreira et al. 2007). For instance, Barde and Owens (1996, 11) conducted a study on the application of eco-taxes in OECD countries and found that in those countries “The ‘greening’ of taxes can be done in two complementary ways. One involves the restructuring of existing taxes by raising the relative prices of products (...) that generate more pollution (...). A second approach is to introduce new ‘eco-taxes’ specifically aimed at raising the prices of products which create pollution. . .” and Álvarez et al. (1998) evaluated the type of Green Tax Reform in some pioneer countries in its implementation and proceeded to its classification. According to these authors the Green Tax Reforms can assume two different types, depending on the extent of the reforms implemented: **Partial Reforms** (adaptation of the existing tax system to give it an environmental concern) or **Integrated Reforms** (giving rise to an innovative tax system, where environmental taxation plays a major and preponderant role). Some Nordic countries as the Netherlands, Denmark, and Sweden have been pioneers in the implementation of integrated Green Tax Reforms. Borrego (2016) replicated the study of Álvarez et al. (1998) in Portugal and classified Portuguese green tax reform as a partial one. Carreira et al. (2007) analyzed the Portuguese tax legislation and found that the tax system was beginning to show signs of environmental concerns.

There are also studies that refer to the resistance of organized industrial lobbies against the application of Green Taxation. In this context, Daugbjerg and Svendsen (2001) and Svendsen et al. (2001) argue that Green taxation is against the interests of the polluters and some of them can easily mobilize resources to move political influences, in order to put barriers to such type of taxation.

In addition, in the last years, a few studies, that aim to quantify the impact of Green Taxation on the environment, have also emerged (Alberini and Bareit 2017; Ciccone 2014; d’Haultfoeuille et al. 2014). For instance d’Haultfoeuille et al. (2014)

analyzed the effect of the introduction in France, in 2008, of a bonus/malus system (tax benefits or penalties) on car purchasing: for the least polluting, it was conceded a benefit and for the most polluting it was applied a penalty. The authors found that this environmental tax measure had a negative effect on the environment, as the measure was poorly designed and still applied benefits to the purchase of vehicles that had a considerably high level of pollution. Alberini and Bareit (2017) replicated an identical study in Switzerland and obtained similar conclusions. Ciccone (2014) sought to assess the impact of the tax penalty on the purchase of polluting vehicles introduced, in Norway, in 2007, to the purchase of new, less-polluting vehicles, and found that the impact had been positive on the increase in the purchase of less polluting vehicles.

Lastly, it is relevant to understand this topic from a previous literature perspective, but also to understand its potential for future research. In the context of Green Taxation, there are several future research lines that can be explored, from which the following should be highlighted.

Based on the concern for the planet’s sustainability and the relation between green taxation and the circular economy, it is necessary to identify the green tax reforms performed by the different countries or regions, in order to assess how they actually contribute to the environmental preservation.

At the same time, in a close relationship between green taxation and Circular Economy, it is important to analyze how green taxes contributed to effective changes in economic agents and consumers’ behavior, by influencing their investment decisions, manufacturing and exploration methods, consumer habits, among other attitudes/decisions with environmental impact.

It is not, therefore, enough the creation of green tax measures; it is necessary to monitor their impact in the environmental context, seeking to understand the determinants of their success or failure, contextualized in the cultural, environmental, and even historical specificities of the countries. Thus seeking to contribute to the creation of innovative environmental tax policies, but also assertive in the objectives that they intend to achieve.

It is also important to bear in mind that, in relation to environmental tax measures aimed at promoting more environmentally responsible citizens and companies' behavior, the greater the environmental success of the measure, the bigger is its tax "cost," so it is important to quantify the amount of uncollected tax or of the tax benefit granted to understand its impact on tax revenue.

It is important to highlight that a new methodological approach is desirable, leading to the construction of an index of green taxes, which aims to measure the contribution of a tax system (or specific tax) to the preservation of the environment, which will allow the analysis of the evolution, both in relation to the same country and between countries.

Key Issues

The Green Taxation, in the law context, is classified, as referred to by Nabais (2005), as a form of State intervention in favor of the fight for environmental protection and it falls within the sphere of extra-taxation, that is "a set of rules which only formally form part of the tax law, because their main or dominant purpose is the attainment of certain economic or social results and not the obtaining of revenues to cover public expenditure" (Translated from Nabais 2005, 336).

In the tax systems context, Green Taxation may be the result of an integrated tax reform, that is, by substituting the traditional taxation, or alternatively, it may appear as additional rules to traditional taxes without replacing them. In addition, green taxation can take the form of taxation on consumption, corporate, and individual taxation, among other forms.

Summary

Green taxation is the use of taxation to encourage taxpayers' good behavior in the environmental context. Green taxation is thus a powerful tool for the environment. Taxpayers, in order to obtain tax benefits or to avoid paying higher taxes or fees, adopt more environmentally responsible behavior.

Green Technology for Food Sustainability

Ruhan Aşkin Uzel

Food Processing Department, Yasar University, Bornova-Izmir, Turkey

Synonyms

Clean technology for food sustainability; Eco-technologies for sustainable food sustainability; Environmentally friendly technologies for food sustainability

Definition

Green technology is increasingly being applied in different areas of the food sector (Zaffar 2018). The most important reason for this is the increase in awareness and sensitivity concerning environmental protection in food production and consumption (Shafiei and Hooman 2017). For example, stricter regulations about the chemicals used in food production and the problems that arise from waste processing have prompted manufacturers to find new, alternative methods which cause less damage to the environment. In this context, green technology in the food industry plays a major role in food sustainability. These technologies and techniques include, among other things, wastewater treatment, solid waste treatment, reducing the environmental footprint, climatic intelligent food production, and green extraction (Kesavan and Swaminathan 2018). Using these and similar sustainable food production techniques has now become a necessity in the production process. This is because the levels of production obtained as a result of these techniques is either very difficult or impossible to achieve

with more traditional techniques, while at the same time ensuring sustainability and complying with relevant regulations and public expectations. Therefore, these applications have both technical and economic potential (Tambovceva and Tereshina 2018).

Introduction

Food plays a vital role in human life. Food production systems have therefore predominantly evolved in local systems and then been transformed into more complex global networks of production, consumption, and trade. In this way, the global food system incorporates many national, regional, and local food systems. These systems interact with people's lives, industry, and nature. Therefore, it is also linked to population. The world's population is expected to be 8 billion in 2030, which means that an increase of 50% in food supplies is forecast for that year (Akinwale et al. 2011). Accordingly, as the world population increases, the consumption of resources will increase. In this case, there will be reflections to the industry. Increasing demand for food as a result of world population growth necessitates changes in food production and consumption because there are at least 1.3 billion people whose lives depend on food and agriculture-based livelihoods (Fanzo 2018). However, the food and drink industry consumes 5.3% of global industrial energy, and the European food and drink industry accounts for 1.8% of Europe's total water use. Therefore, for the future of the world, resources need to be managed efficiently and strategies developed for sustainable food production. Therefore, the idea of "sustainable development" or "sustainability" has become increasingly prominent across the globe, and applied and discussed at international, national, regional, and communal level including food (Bibri et al. 2020). All resources involved in food production need to be used as efficiently as possible. More innovative approaches will improve the sustainability of food production. This can be by adapting to modern production technologies, such as Industry 4.0 principles.

Progress in food production also affects developments in other areas, such as environmental protection, the circular economy, biodiversity, and importantly, the development of green technology.

Green technology is the use of science and technology facilities to produce environmentally friendly products (Guillard et al. 2018). The term is also used for the use of clean technologies to produce goods (De Melo et al. 2014). As an example, green technology is a concept that is intertwined with many areas of food production, from farm to fork (Zaffar 2018). It can be used in place of many expensive and environmentally unfriendly technologies. Processes using green technology bring sustainable production in many areas. Besides environmental practices, the processes in which sustainable production principles are applied also support political and social sustainability, because economic, environmental, and social dimensions are among the basic elements of sustainable development (Klarin 2018).

The sustainability flow facilitated by green technology is nature-friendly. While meeting the needs of people, it tries to do it with the least waste and in the most economical way (Kristinsson and Jörundsdóttir 2019). From this point of view, it is appropriate to consider the concept of sustainability, which comes with the use of green technology, on the basis of social, economic, and environmental factors. In summary, the current chapter includes information on the applicability of green technology and sustainability, the sectors that it addresses, and the advantages of sustainable food production.

Green Technology

Green technology is a very comprehensive term that blends economic and environmentally friendly technologies in daily life. One of its most powerful characteristics is that it protects natural resources. For example, with the use of green technology, it is possible to reduce the use of fossil fuels, because the fossil fuels such as oil and coal are some of significant factors in global warming. When they are burned, they produce

pollutants. The pollutants decrease oxygen level, increase carbon dioxide level, and are contributors to acid rain, causing global warming (Oleksy 2018). Another example of green technology is the use of technology to generate energy from the sun. The use of photovoltaic panels producing electricity from the sun on roads and pavements is one of the uses in this scope (Xiang et al. 2018). In the food industry, green technology is used in alternative energy use for food dehydration applications, creating a green supply chain, eco-label applications, and using bioplastics as packaging (Clark et al. 2016). Hence, the scope of green technology is very wide (De Melo et al. 2014). It is sometimes difficult to subcategorize its activities. But it can be clearly stated that the green technology is accumulation of activities that protect balance in nature. In other words, it is a unity of technological tools that can be used to meet the needs of people without destroying the natural heritage that passes down from generation to the other in society.

Sustainability

Sustainability is literally defined as maintaining the ability to exist while ensuring the continuity of diversity and efficiency (Surampalli et al. 2020). There is now a general consensus that world resources and the environment are moving towards the exhaustion limit as a result of human activities. Sustainability, which is considered from this point of view, can only be achieved by using the resources offered by nature at a speed that allows them to be renewed automatically (Armanda et al. 2019). The use of the concept of sustainability is flexible. It is possible to use this concept in ways such as sustainability of food production, sustainability of forests, sustainability of wetlands, sustainable cities, sustainable agriculture, and sustainable architecture (Surampalli et al. 2020). The concept of sustainability is also related to the definition of sustainable development that constitutes the basis for the concept of sustainable development, which is one of the main parameters in the development and welfare levels of societies. The introduction of the concept of

sustainable development in the global sense was first made in the report entitled *Our Common Future* by the World Environment and Development Commission (Bruntland 1987). In this report, sustainable development was defined as the development that meets the daily needs without endangering the ability of nature to respond to the needs of future generations. While using resources, it also needs to be renewed. If this balance in the use of resources is established healthy, the balance of natural resources will not be damaged (Tu et al. 2019). Because, human life depends on natural resources, but these are not infinite (Fernando et al. 2019). At this stage, the concept of sustainable development comes into play. Sustainable development means creating a balance between nature and humanity (Klarin 2018). This balance is provided by all beings (Bibri et al. 2020). Ensuring the sustainability of the balance in the use of resources is a product of success in the management of the process. In other words, concepts such as technology, environment, energy, natural resources, and their connection with each other should be well understood in order to ensure a good balance in resource use (Fernando et al. 2019). For example, it is not possible to ignore the factor of environmental protection in a food production where natural resources are used effectively. At the same time, this production must be well planned in terms of energy use. In addition, this production is expected to contribute to the country's economy within a sustainable framework. Therefore, sustainability is a holistic concept (Surampalli et al. 2020). The concept of food sustainability can be considered as one of the prominent dimensions of sustainability in terms of increasing world population, increasing new resource requirements, rising energy prices, and climate change (Shafiei and Hooman 2017).

Food Sustainability

Basically, the food industry processes agricultural raw materials into food and beverage products. Food sustainability, of course, aims to produce good quality food. Besides, the concept of food sustainability implies sustainability principles to a wide process ranging from raw materials to

equipment to be used in the production of quality food products, from packaging to waste (Surampalli et al. 2020). Among the topics evaluated in this context, it is necessary to evaluate different parameters such as energy consumption, the minimization of greenhouse gas emissions, resource and waste management, water and wastewater management and packaging, coordination of agricultural activities, food transportation, and assessment of environmental impacts (Armanda et al. 2019).

Sustainable Food Production

Sustainable food production involves transforming agricultural raw materials into quality, healthy food and beverage products by taking into consideration all the processes, from production to consumption, from raw material procurement to water and energy use, from resource utilization to waste management, and from packaging to distribution channels (United Nations World Population Prospects 2015 revision). It is predicted that food production will have to increase by at least 70% by 2050 in order to satisfy an increasing population and settlement levels. However, the increased demand for habitable land as a result of the expanding population will cause tensions because more agricultural land will also be needed to satisfy food demand. Limited water and energy resources will also push the community to find alternative solutions to establish a sustainable life (FAO 2009). In addition to this problem, sustainable food products must contain a sufficient and balanced composition of energy and nutrients that support health, that is, the nutrients of these foods need to be varied and intensive (Kesavan and Swaminathan 2018).

As one of the requirements for a sustainable life, the principles of sustainable food production must be applied correctly. The methods used should address the principle of environmental protection, which is one of the fundamental principles of sustainability and should have global awareness. Global food production methods also need to change to minimize their negative impact on the environment and support the world's future food production capacity. As in other

human actions, food production has an impact on climate change, drought, soil degradation, and destruction of biodiversity (Charles et al. 2014). It is estimated that 25% of global greenhouse gas emissions are directly caused by grain production, livestock, and forestry. Cereal and livestock sectors use 70% of fresh water resources and cover up to 60% of the earth with forestry (Rojas-Downing et al. 2017). Thus, it is necessary to consider the concept of sustainable food production on a larger scale. That is, instead of thinking that this concept serves only food production in quality, it should be evaluated as a whole, including preventive activities along with producer and consumer and environmental factors.

The European Commission is examining how best to reduce the environmental impact of food production and how to limit waste in the food supply chain (Taghikhah et al. 2020). It is possible to reach this goal through the use of current technologies and technical knowledge (Sala et al. 2017). In order to adapt food production to the principles of sustainability, a number of institutions have devised plans to use natural resources more efficiently, better preserve natural resources, protect marine resources, produce food from sustainable sources, use environmentally friendly food packaging techniques, and reduce food waste (Zaffar 2018). For example, it is expected that the area suitable for food production will be planned in a geography that is efficient in terms of energy and water use. Or, it is preferable to position the food production company in an area compatible with the raw material supply in order to ensure that the transportation of the raw material to be used in food production is economical and that the environment and product quality are not adversely affected. In addition, fertilizers and pesticides have been started to be used more responsibly to prevent water and soil pollution. Also, raw materials for food packaging are selected from low-priced cellulosic materials that are recyclable and biodegradable (Kamani et al. 2019). The use of new forms of food packaging materials to replace the unsustainable ones is the other one of the steps taken in this direction (Nielsen et al. 2020).

Types of Food-Related Green Technologies

Wastewater Treatment

With the acceleration of industrialization and population growth in recent years, existing water resources are being exhausted and polluted rapidly. This situation brings with it an increase in the need to provide water and food and causes a shortage of water (Molden 2013). Hence, efficient use of water resources is a critical topic, regardless of whether the waste treatment technique is conventional or more modern. As well as the removal of undersirable substances from water, the other important issue is the technique used in the water treatment process. The technique used for wastewater treatment should be consistent with the principles of sustainability. In other words, there has to be environmental awareness or social and environmental responsibility for the technology used (Surampalli et al. 2020). Traditional methods for wastewater treatment use physical, chemical, and biological treatment processes (Crini and Lichtfouse 2019). In recent years, wastewater has begun to be evaluated differently from the materials that need to be disposed of. Due to the

water and nutrient content of wastewaters, wastewater becomes a kind of raw material and the techniques used in the treatment of wastewater are developing rapidly.

These approaches are based on the principles of green production. Green production engineering, as a sub-branch of food and chemical engineering, contributes to environmental protection within the framework of sustainability (Fig. 1) and is very suitable for innovation in the field of wastewater treatment. Figure 1 shows the basic elements that are necessary for the implementation of environmental sustainability principles. This structure has an importance to understand how sustainability, environmental protection, and green engineering principles are linked to each other and are implemented. If the principles of sustainability are not known, information cannot be obtained about the principles to be adopted for environmental protection. Since the sum of these elements is an input for awareness building in green engineering practices, it is difficult to link green production with environmental sustainability in a situation where the concept of sustainability is not briefly mentioned.

Green Technology for Food Sustainability,

Fig. 1 Relation of green production with environmental sustainability (Sezen and Cankaya 2013)

Examples of modern techniques used in this context are the use of green technology. Green technology can be recognized as a cheaper and technically emergent method for wastewater treatment, and provides an alternative to the high cost of conventional steps (Neoh et al. 2016). It has become increasingly more important in the food and chemical industry. In green wastewater treatment, the balance of oxygen and carbon dioxide is considered, along with alternative ways to clean wastewater. Examples of green technology approaches include the adaptation of modern biofiltration techniques; new-generation bioreactor designs; a new bioremediation approach; and electrowinning and electrocoagulation techniques. Integration of membrane bioreactor with various wastewater treatment systems is one of application areas of green technology (Neoh et al. 2016). In this process, small molecular weight of organic micropollutants can be retained compared to conventional activated sludge process. This process offers advantages such as having smaller footprint, less sludge production,

higher separation efficiency, and highly improved effluent quality as compared to conventional activated sludge treatment (Esquivel-Hernández et al. 2017).

Solid Waste Treatment

Solid waste treatment is another technological approach that is used in green food production (Fig. 2). The solid waste management hierarchy aims to evaluate all waste management steps as a whole and to ensure sustainability both environmentally and economically (Antonopoulos et al. 2014). Effective waste management is possible only by combining all methods. According to the solid waste management hierarchy, the most preferred step is to prevent and reduce waste at its source. In cases where waste production cannot be prevented, reuse and recycling stages are applied. For waste types where recycling is not possible, landfill method is also implemented. When ordered from most preferred to least preferred, the basic elements that make up the solid waste management hierarchy can be specified as

Green Technology for Food Sustainability, Fig. 2 Solid waste treatment hierarchy (Antonopoulos et al. 2014)

waste disposal, waste treatment, energy recovery, waste recycling, waste reprocessing, and waste avoidance. For an effective integrated waste management, waste characterization, performance conditions, reliable data, and sufficient cost information are required (Guerrero et al. 2013). According to all this information, waste management steps are determined. The importance of the use of natural resources in food production as well as the method of disposal of solid waste after production are core issues for solid waste treatment applications (Shadi 2015). It is important to manage waste because the process not only relates to its disposal. The type and quality of materials used in food production and the technical knowledge of the processors are all important issues. The philosophy of eco-friendly process construction should also be based on solid waste management (Ulucak and Khan 2020).

Open burning, dumping into the sea, incineration, and hog feeding are some examples of traditional solid waste treatment methods, all of which have disadvantages. However, researchers in the food industry have developed some sustainable techniques using green engineering and waste/energy management to provide alternative processes.

Reduction of Ecological Footprint

As the impact of environmental problems becomes ever more evident, new concepts are emerging to draw attention to these problems. The concept of ecological footprint is one of them (Galli et al. 2016). Ecological footprint is a method developed to calculate the burden that a certain population has on nature as a result of production and consumption activities and to determine how much it should return to the ecosystem (Mancini et al. 2016). These methods measure the biocapacity needed to reproduce the natural resources consumed by an individual, community, or a specific human activity and, if possible, eliminate the resulting waste through current technology and resources. Biocapacity is shown in a global hectare (kha) unit (Labib et al. 2018).

A number of concepts are used in the calculation of the ecological footprint: the consumption

footprint, ecological footprint of production, farmland footprint, forest footprint, grassland footprint, construction footprint, fishing field footprint, carbon retention footprint, global hectare, ecological deficiency, and ecological reserve. Some of them are expressed in Table 1 (Wu et al. 2019). When these areas are examined, it is seen that food production comprises all of them. The carbon footprint effect of the components specified in the table is more than the effects of all other components. The carbon footprint, which accounts for about 60% of all damage, is also considered the fastest growing one (Mancini et al. 2016). Carbon footprint measures carbon dioxide (CO₂) emissions associated with fossil fuel use (Pandey et al. 2011). For example, the use of fossil fuels such as coal, oil, and natural gas during manufacturing process directly results in carbon emissions in an organization. Likewise, gasoline that a person burns in order to drive his car releases a certain amount of carbon directly into the atmosphere. In the ecological footprint calculations, the measured amounts for CO₂ are converted into biologically productive areas necessary for absorbing this CO₂ (Labib et al. 2018). In order to make a reliable measurement system in terms of sustainability within the concept of the ecological footprint, it is also necessary to convey

Green Technology for Food Sustainability,
Table 1 Six main areas of ecological footprint (Wu et al. 2019)

Number	Area name	Definition
1	Carbon (energy)	Forest area that will be required to absorb carbon dioxide from individuals' energy consumption
2	Farmland	The grain area that will be required to produce cereals consumed by the individual
3	Grassland	Grazing area required to produce the required animal products
4	Forest	The amount of forest area required to produce wood and paper
5	Fishing	You will have to produce sea fish and seafood sea area
6	Construction	The land area you will need to build residential areas and infrastructure

information and results by an authorized organization. One of the institutions established to achieve these goals is the Global Footprint Network (GFN). GFN provides a key indicator of sustainability in order to measure the human impact on the planet's ecosystems (Galli et al. 2016). This indicator examines the balance between natural resource supply and demand arising from human activities. As it can be seen from the developments, some new methods should be established in order to reduce ecological footprint (Ulucak and Khan 2020). Green technology can be given as an example (Neoh et al. 2016). It is clear that applying green technology in food production supports the sustainability principle by reducing the ecological footprint. Because, energy is efficiently utilized in green technologies then it will help to reduce the harmful environmental effects (Kamani et al. 2019). For example, food-enzyme engineering is an area that has been implemented for many years. The use of enzymes in the reduction of the ecological footprint in the context of green food production is achieved through life cycle assessment (LCA) (Oxenboll and Ernst 2008). The LCA method allows for the environmental impacts of different food production techniques to be communicated to users and enables users to make comparisons. The use of enzymes as environmental biocatalysts to reduce the ecological footprint can be given as an example of an innovative green technology application (Jegannathan et al. 2011). Enzymes help to reduce the waste that is produced after agri-food raw material processing. Therefore, they help protect the environment and reduce material requirements in the process steps, thus leading to a decrease in carbon footprint by applying "green production" in modern approach compared to environmentally unfriendly methods.

"Climatic Intelligent" Food Production

Food safety is a concept with many subdivisions in theory and practice. In these subdivisions, some area-specific parameters are used such as quality, biochemistry, health, shelf life, contaminants, etc. (Cao et al. 2019). These parameters associated with the concept of food safety include demographic structure, diet, climate change, food

waste, food storage conditions, food production capacities, the income status of consumers, and environmental effects on food. It is also possible to see the impact of environmental conditions on each of these parameters. Moreover, even their interaction with each other can create a new assessment dimension for the field of food safety (Tsagkaris et al. 2019). For example, trying to reduce food loss and production waste can result in savings in food consumption. This may also reduce acceleration in new food demands within the scope of environmental protection, food loss, and food waste because the factors from production to consumption will be reevaluated by the producer and the consumer by considering the food safety parameters (Galanakis 2019). Hence, the issue of reducing food waste plays a decisive role in the protection of environmental balance, and the efficient use of resources. In this context, ways can be determined to adopt green food production principles for sustainable food production and food safety. Application of green technology is one of them. In this way, a significant reduction in greenhouse gas emissions could be achieved in food sector. Sustainable and eco-friendly management practices within the scope of green technology practices, as well as product innovation, promote efficiency in resource use (Fernando et al. 2016). This is of great importance in food production, which may be based on limited process opportunities (Hiç et al. 2016). For this reason, food storage conditions, food production capacity, and climate conditions can be evaluated within the scope of green technology applications. However, there is a need to determine a strategy to manage interactions between food safety parameters. Otherwise, changes in environmental and economic conditions for the coming years may lead to fluctuations in food supply demand and quality (Taghikhah et al. 2020).

In this context, the possible disadvantages arising from climate change, which is one of the other parameters for food safety, can be reduced by using appropriate production techniques. In addition, climate change needs to be taken into account different production plans, such as urgency in dealing with illness-related disruptions, the need to take measures against disasters,

and the need to make area-based investments. These plans provide confidence in the food chain as well as reinforcing food safety elements (Cao et al. 2019).

Climate change is likely to harm food safety and may also reduce agricultural productivity as it directly affects all living organisms and their ecosystem, which is formed as a result of their mutual relationship with the sterile environment that surrounds them, through health, water resources, and nutrition, and especially natural disasters (Scheub 2016). In this context, the agricultural sector is considered to be the most likely to be affected by climate change, as it is directly dependent on nature, climate conditions, and weather conditions. In addition, the ability of agricultural activities to provide vital resources increases the importance of climate change in this area (Rojas-Downing et al. 2017). To decrease these potential impacts, producers may need to use innovative technologies, sustainable agri-food production techniques, and other innovative technical options, such as the production of biodegradable bioplastics, the development of innovative irrigation techniques, and the establishment of a gray water recycling system (Zaffar 2018). In this context, new initiatives such as the production and distribution of climatic smart food and adaptation strategies to implement new food systems are being developed within the scope of green food production. These initiatives will both make food safer and serve the authorities' goal of mitigating climate change.

Green Extraction

Extraction of natural products has been carried out probably since the discovery of fire. Prior to extraction, people tried to extract materials by immersing them in basic solvents like water, oil, etc. (Uzel 2018). Many civilizations from East to West such as Egyptians, Phoenicians, Arabs, Indians, Greeks, Romans, etc. applied various extraction methods including maceration, distillation, etc. to produce foods, perfumes, and natural extracts (Esquivel-Hernández et al. 2017). Extraction is the transfer of one or more compounds in the solid or liquid phase to another liquid phase using the different solubility properties of the food

material (Zia et al. 2020). The extraction step is an indispensable part of most analytical processes. In recent years, there has been an increasing demand for advanced extraction techniques (Zia et al. 2020). Because, advanced extraction techniques such as microwave extraction, ultrasound-assisted extraction, and the use of pulsed power technology in extraction have advantages such as short processing time, preserving the natural properties of the material, and being cheaper and more environmentally friendly (Belwal et al. 2018). The reason for this is that it is suitable for automation, short extraction time, reduction in organic solvent consumption and in sample preparation, and prevention of pollution in analytical laboratories (Uzel 2018a).

Parallel to the development of new technologies, the basic understanding of extraction principles in green food production has advanced. The extraction that applies the principles of green production is called green extraction which reduces energy consumption and allows use of alternative solvents and renewable natural products while ensuring a safe extract and quality (Uzel 2018b). Progress in extraction technology has led to new trends in sample preparation. Therefore, conventional extraction techniques in which conventional organic solvents are used for the recovery of bioactive constituents from food material with or without heat treatment have been replaced by nonconventional extraction techniques that extract bioactive constituents in a shorter time with higher recovery capacity such as microwave-assisted extraction, supercritical fluid extraction, and pressurized liquid extraction (or accelerated solvent extraction) (Esquivel-Hernández et al. 2017). Purpose of all these techniques is to obtain or isolate the desired compound out of food materials. The similarity in these conventional and nonconventional green extraction methods, which is based on the principles of mass transfer and diffusion, is the possibility of operating at high temperature and pressure, which significantly increases the speed of the extraction event (Esquivel-Hernández et al. 2017).

The green extraction technique has many advantages over conventional techniques. For example, it does not harm the natural structure of

the food product, it is lower in cost than nongreen techniques, it is easy to apply, it does not harm the natural structure of the food and the solvent used, and the processing time is short (Fig. 3). Because the resources can be managed efficiently in green extraction technology, it results in cost reduction and in better use of energy. The extraction process uses clean solvents such as water and reusable CO₂ that are environmentally friendly. After extraction, CO₂ can be eliminated and recycled by lowering the pressure and the extracted compound can be recovered without solvent residue. This reduces the number of steps in post-extraction treatment. The before- and after-extraction processes are simple as well as practical during sample preparation and processing. It is enough to control the process temperature and pressure during the extraction process (Esquivel-Hernández et al. 2017). Some green extraction techniques are discussed below.

Pressurized Liquid Extraction (PLE): One of the new extraction techniques, pressurized

liquid extraction (PLE), is also called accelerated solvent extraction (Belwal et al. 2018). PLE equipment has a sealed high-pressure extraction cell that maintains the food sample, allowing higher temperatures and pressure to be applied during the extraction process. The elevated pressure allows the extraction solvent to be in liquid form at higher temperatures. Subcritical water extraction or pressurized hot water extraction is a typical example of PLE. In this extraction technique, it is possible to use water as an extraction solvent. The extraction system utilizes water below critical conditions. Critical conditions consist of two terms: critical temperature and critical pressure. The critical temperature is the value at and above which the vapor of the solvent cannot be liquefied, no matter how much pressure is applied. The critical pressure is the value above which the characteristic liquid and gas behavior of the solvent do not exist. Hence, when the critical temperature and critical pressure are reached, the gas and liquid solvents result in only one phase,

Green Technology for Food Sustainability, Fig. 3 Some advantages of green extraction technology (Esquivel-Hernández et al. 2017)

the supercritical phase, having the same properties. The critical temperature and pressure of water that is used in PLE applications are 374 °C and 22.1 MPa, respectively (Nakilcioglu and Otles 2014). Hence, the water used as the extraction solvent in PLE systems can be safely used in order not to cause harm to the environment. For this reason, this extraction technique can be evaluated as a green extraction application. The use of water is important because it reduces extraction cost and is environmentally friendly because it results in nonsolvent waste (De Melo et al. 2014).

Microwave-Assisted Extraction (MAE): Microwaves are high-frequency electromagnetic waves (300–300,000 MHz). The principle of heating using microwave energy is based on the direct effect of the microwave on the molecule through the transmission of ions and the dipole rotation. In most applications, these two mechanisms occur simultaneously. In this way, ionic conduction, which forms the basis of microwave-assisted extraction, is realized. Ionic conduction is the electrophoretic migration of ions when a magnetic field is applied. The solution used in extraction resists this ion flux and the solution heats up with the effect of friction. Microwave-assisted extraction produces the ability of microwaves to absorb energy in conjunction with the dielectric constant of polar chemicals which is utilized while the principles of ionic conduction are used. Microwave-assisted extraction can be applied using two different techniques. The first one is a closed-vessel application where the temperature and pressure are under control. The other is an open-vessel application, where the system is under atmospheric pressure. Microwave-assisted extraction enables faster heat generation, shorter extraction times, and extracts in better quality. It has been reported that it also reduces solvent consumption and increases the efficiency of the extraction. It has been proposed as an efficient, economical, and environmentally friendly method in the literature (Uzel 2018a). Microwave applications have been used in the food industry for different purposes for many years (Silva et al. 2010). With this application, the efficiency of the extraction process can be increased (Uzel 2018a). Its advantages include being time- and cost-

effective, and not harmful to the environment. Considering also that microwave-assisted extraction can decrease or eliminate the utilization of organic solvents during extraction, it can be regarded as a green extraction technique (Silva et al. 2010).

Pulsed Electric Field (PEF)-Assisted Extraction: PEF is one of the nonthermal food processing methods. The basic principle of the pulsed electric field system is that the food material placed between two electrodes is exposed to short and intense electric pulses at micro- or millisecond intervals and at an impact intensity range of 10–80 kV/cm, and the bioactive compound to be extracted is released from the food material (Donsi et al. 2010). Compared with traditional methods, pulsed electric field applications have been observed to produce better quality products due to enhancement of mass transfer of water and valuable compounds to be extracted from food materials (Mohammed and Ayman 2012). In this technique, the sensory properties and physical quality changes of food can be kept to a minimum. One of its biggest advantages is that it can be used effectively in the inactivation of microorganisms by keeping the nutritional value, color, texture, and aroma in the best way due to the low process temperature in unprocessed foods. At the same time, the energy efficiency of the pulsed electric field process is high and the product is obtained at minimal cost. In recent years, PEF-assisted extraction has been used in several fields such as extraction of valuable compounds from biological materials in food processing, biotechnology, and medicine for the introduction of different molecules into the cell, etc. (Blahovec et al. 2017). Using the PEF extraction technique, it is also possible to reach a remarkable yield at low temperature even if water is used as a solvent. Thus, the environmental benefit of the PEF technique can be clearly seen (Kokosa 2019).

Supercritical Fluid Extraction (SFE): SFE is defined as the dissolution and recovery of food stuff in a fluid under supercritical conditions that is above critical temperature and critical pressure values. Critical temperature and pressure are conditions in which the solvents used in the extraction behave as if they are in a single

phase, called the supercritical phase, regardless of their physical states (Nakilcioglu and Otlles 2014). Following extraction, the targeted extract is separated from the extraction fluid by reducing the pressure (De Melo et al. 2014). One parameter that is related with supercritical fluid extraction is the density of the supercritical fluid. The density can be controlled using changes in temperature and pressure. The supercritical fluids are selected according to the application in which they are to be used and are chosen by reference to their cost; availability; nonflammable and non-combustible properties; not being harmful to the environment or product; and being inert. Another important parameter to express the supercritical fluid extraction efficiency is thermal conductivity. The thermal conductivity (λ) of a material is a measure of its ability to conduct heat (Xu et al. 2018). It varies with temperature, pressure, or density of the liquid, and under supercritical conditions. It decreases with increasing temperature. Hence, supercritical fluid extraction process can be regarded as one of techniques that applies green technology principles (Zia et al. 2020).

Summary

Food production is a process in which agricultural resources and raw materials are organized to meet the needs of people. Sustainability of this process is one of the basic requirements of sustainable food production. Sustainability as an element of sustainable development is essential for the management of development plans of almost all countries (Armanda et al. 2019). Although definitions about sustainable development may vary, it is based on three basic approaches: economic development, environmental sustainability, and social integration (Mantlana and Maoela 2019). The differences in the structure of societies also make the size of the intersection sets of these three approaches different. Therefore, the application of green technology is one of the key components in ensuring the welfare of a society by referring to the relation between economic and environmental developments and social integration aiming to

provide social welfare, economic advantage, and environmental protection. Hence, it can clearly be seen that the green technology offers new perspectives such as wastewater treatment, solid waste treatment, reduction of ecological footprint, “climatic intelligent” food production, and green extraction for sustainability in food production. These include an enhanced concern for the quality and safety of food products, increased preference for natural products over synthetic ones, and broadened regulations related to nutritional and toxicity levels of active ingredients. They also have driven green food technology to become the primary alternative to conventional food production methods that have various drawbacks such as high cost, long process time, low yield, etc. The increase in the number of products that are produced using green production techniques increased awareness in consumers to discuss new discoveries in the field. For instance, they are willing to pay more attention for green products that are produced by using green technologies in order to contribute to environmental protection for the development and welfare of society (Boztepe 2012). To conclude, it can be stated that with increasing concern about the use of food production methods, green technology is gaining popularity faster than ever before. The future looks promising for the use of green technology, with new sustainable techniques being developed for other novel uses in the food processing industry.

Definition

The green economy has been defined as a low-carbon, resource-efficient, and socially inclusive economy that serves as a vehicle to achieve the Sustainable Development Goals (SDGs) by improving people's well-being and social equity while also protecting the planet from resource exploitation and environmental risks (Georgeson et al., 2017).

The SDGs establish a new imperative for the green economy, paving the way for more environmentally friendly technologies and investments (Jänicke, 2012). These latter include a variety of activities, actions, and programs carried out by institutions as well as public and private organizations in order to increase energy and resource efficiency, protect biodiversity, reduce pollution and carbon emissions, and generate employment and human well-being. The green economy is based on long-term development because it helps to shift the economy's focus (in terms of investment, capital and infrastructure, employment, and skills) to positive social and environmental outcomes around the world.

Introduction

The green economy emerged as a key policy imperative at the United Nations Conference on Sustainable Development (Rio + 20) in 2012, but the concept dates back to the late 1980s (Pearce et al., 1989). Since its inception, the green economy has regarded natural assets (also known as “commons”), such as natural capital, considered critical to both the economy and society (Bailey & Caprotti, 2014; Barbier, 2012; Ferguson, 2015).

Despite its popularity following the financial crisis, the green economy concept has now been internationally disseminated and is considered a pillar of global, regional, and national policies (Bina, 2013; Bina & La Camera, 2011; Schmalensee, 2012; Tienhaara, 2014).

The project “Inclusive Green Economy Policy Making for SDGs: From Implementation to Evaluation” within the European context aims to achieve the aforementioned objectives through

two main elements. The former – Development and Implementation of an Inclusive Green Economy Policy Review methodology – is finalized to analyze countries' experiences with green economy policy implementation as well as their existing frameworks for selected SDGs. The review, which has been piloted in three countries, assesses the progress of key sectors as well as selected cross-sectoral policies. The latter, titled “Further Development and Application of an Integrated Green Economy Modelling Tool,” aims to improve countries' understanding of the cross-sectoral impacts of inclusive green economy policies while also tailoring the modeling tool to a specific country's context and sectoral focus. Therefore, it advocates for a meso and regional approach to sustainable economic growth through regional, sub-regional, and national policies covering green finance, technology, and investments and assisting countries with mainstreaming macroeconomic policies to support the transition to a green economy. Furthermore, the green economy is founded on some fundamental pillars that should guide the socioeconomic behaviors of businesses, citizens, and institutions at both the macro and micro levels: sustainable consumption and production, as well as resource efficiency. On the one hand, the goal of reducing waste generation and emissions across the entire life cycle of processes and products should drive both consumption and production (Fig. 1). On the other

hand, resources should be used to create value for society as a whole, while the amount of resources required, as well as of emissions and waste generated per unit of product/service, should be reduced.

The green economy takes into account the critical interdependence of the economy, society, and environment. Its promotion is dependent on collaboration among various stakeholders (multi-stakeholder collaboration), which is essential for supporting and strengthening long-term changes in consumption and production patterns. UN Environment (UNEP, 2011) has increased its engagement with the private sector, which is a key actor in promoting the green economy, in addition to governments and non-profit organizations.

Key Issues

The concept of green economy is frequently associated with those of circular economy and bio economy, which share the goal of reconciling economic, environmental, and social goals. “The three concepts are currently mainstreamed as key sustainability avenues in academia and policymaking” (D’Amato et al., 2017, p. 716). However, such concepts are based on different assumptions and manifest in various ways. Green economy can be assumed as a mainstream

Green, Circular, and Bio Economy, Fig. 1 The pillars of sustainable consumption and production. (Source: Abaza, 2012, United Nations Development Programme (UNDP))

concept for environmental sustainability, incorporating features relative to circular and bio economies such as eco-efficiency, renewables, and nature-based solutions (Murray et al., 2015; OECD, 2011). While the circular and bio economies are more focused on resources, the green economy addresses the role of ecological processes. Furthermore, in terms of the social dimension, the latter emphasizes certain aspects at the local level (e.g., eco-tourism and education).

However, in sustainability research, the three concepts have been considered interconnected (Loiseau et al., 2016), and the relationship between the concepts has been highlighted (Ollikainen, 2014; Székács, 2017). Authors argue for their reciprocal integration by comparing the sustainability strategies derived from these concepts because they all trigger/elicit the path toward a more sustainable economy. Although they are global concepts, “differences at a regional level exist” (D’Amato et al., 2017, p. 716) because they have been contextualized in accordance with specific institutional frameworks and are supported by ad hoc national policies.

Several contributions have highlighted the variation in underlying assumptions and visions, as well as viewpoints and objectives of policies and actions aimed at operationalizing sustainability (D’Amato et al., 2016).

Both circular economy and bio economy are part of the political agenda at a global level. Namely, the EU has formulated bio economy and circular economy policies in the last decade (EC 2012; 2015). Green economy has been promoted internationally by UNEP and has been operationalized through several regional policies (Murray et al., 2015).

From a scientific standpoint, green economy and bio economy predominate over circular economy in the United States (USA, 2012). They are all thoroughly researched in Europe. The green economy debate is most prevalent on a global scale, in both developed and developing countries. Circular economy and bio economy, on the other hand, are more researched in transitional and developed economies. Sustainable development, green investments, tourism, business education employment, recycling re-use, reduction in

product life cycle, renewables in energy production, conservation, and land use are some of the topics covered in green economy research, whose contributions are published in journals focused on environmental, ecological economics, and natural resources. As a result, while the green economy incorporates elements from both the bio economy and the circular economy, topics are more focused on nature-based solutions, green investments, and conservation. Among the major sustainability aspects included in the green economy construct, the following are associated with the environmental dimension: conservation, water, land, biodiversity, food, and security; and the social dimension: sustainable development; green investments, tourism, business, employment, and education. Furthermore, the concepts of green growth and green frugality are included in the green economy (see D’Amato et al., 2017). The former refers to the coexistence of economic growth and environmental sustainability, which is fostered by ecological adaptation and resilience. The latter refers to the use of nature-based solutions to supplement or replace technological solutions, based on an understanding of the ecological limits to growth.

Summary

The green economy is a critical component of the twenty-first century’s sustainable development agenda. Green entrepreneurs are assumed to be the drivers of the transition to a green economy in the current debate because they are key actors in negotiating the tension between the green economy and the mainstream economy in their business activities. Green economy, bio economy, and circular economy are all concepts that embrace the idea of holistic economic growth (Tomaselli et al., 2017). Some authors, however, argue that none of them are based on strong sustainability because unlimited growth cannot be reconciled with strong sustainability (Lorek & Fuchs, 2013). Other authors contend that green economy and circular economy are more focused on long-term sustainability than bio economy (Loiseau et al., 2016). Given the global context, green economy has incorporated key elements of circular and bio

economy, such as clean technology and renewable energy (Eaton, 2013).

Ultimately, considering these concepts as complementary rather than isolated and competing, that of green economy appears to be the most inclusive (D'Amato et al., 2017). All have gained traction globally, attracting the attention of political, economic, and societal actors such as industries, academia, non-governmental organizations, and policymakers, among others. Furthermore, despite their differing assumptions and operationalization strategies, it is critical to highlight the concrete actions and impacts because the three concepts share the goal of reconciling economic, environmental, and social goals.

Director Remuneration; Remuneration Report

Definition/Description

The *Greenbury Report on Directors Remuneration* (1995) (hereafter called the *Greenbury Report*) was one of the first comprehensive governance codes directly addressing executive and director remuneration. The *Greenbury Report* was commissioned by the Confederation of British Industry in response to public concerns over recently privatized public utilities and the salaries and bonuses earned by executives, while they implemented job cuts, and service price increases. The *Greenbury Report* recommended an independent remuneration committee, linking executive

pay to corporate financial and operational performance measures, and increased the requirements for disclosure and transparency on directors' remuneration. However, the credibility of the *Greenbury Report* was challenged due to the composition of the group; it was not deemed to be independent of the sector it was to investigate, and it was argued that its recommendations did not go far enough.

The financial crisis of 2008 highlighted the failure of the *Greenbury Report's* recommendations for limiting excessive executive pay. In particular, the *Walker Review of the Banking Sector* found that performance-based bonus schemes in banking corporations that are supposed to align executive objectives with shareholder objectives increased corporate risk in the period leading up to the financial crisis. In addition, during the crisis, executive pay in large publicly listed corporations (PLCs) continued to increase, while workers' wages stagnated. Therefore, despite Greenbury's recommendations, executive pay continued, and still continues, to be a concern for the public and policymakers alike. Nonetheless, improved transparency on remuneration and a greater linking of pay to performance followed from the *Greenbury Report* and most corporations now include operational measures linked to performance and sustainability.

Introduction: The Problem of Excessive Executive Pay

Corporate governance mechanisms are traditionally seen as devices for reducing agency costs between shareholders and managers. These costs arise from mismatched incentives, information asymmetry, and a belief that executives are self-serving at the expense of shareholders. However, the role of governance is changing. Regulators and governments are increasingly employing governance tools that impose public responsibilities on corporations, including measures that seek to equalize wealth distribution, promote workforce diversity and equality, and pursue environmental objectives (Choudhury and Petrin 2018). The result of this is that executive pay, particularly in PLCs, is deemed to be of interest to a society at large as the public, either directly through

individual shareholdings or indirectly via institutional investors such as pension schemes, invested in them. Therefore, stakeholder theory argues that the public's interests should be protected by the board and not sacrificed for executive rewards. The public is interested in the sustainability of corporations, as this ensures economic stability, a strong financial sector, and employment. Recent corporate failures have increased the public's concern about financial performance-based pay packages that incentivize excessive risk-taking. Further public concerns have also arisen due to actions taken by corporations in response to the financial crisis. For example, many corporations implemented freezes on workers' wages and started to employ workers on a casual basis, using zero-hour contracts. The growth of these contracts have raised broader societal issues of distributive justice and fairness (Villiers 2010), particularly as these austerity measures were not typically applied to executive pay packages.

Background to the Greenbury Report

The *Cadbury Report on Financial Aspects of Corporate Governance* (1992) included recommendations on executive pay and the establishment of a remuneration board subcommittee. Within 2 years of the *Cadbury Report*, excessive executive pay again became a hot issue as politicians highlighted recent utility privatizations that created 50 millionaires among the executives. A key media focus was the 75% pay increase for the chairman of British Gas, Cedric Brown, which resonated with a society suffering from high unemployment, resulting in demonstrations from the public and small shareholders at the corporation's annual general meeting (Jones and Pollitt 2002). The issue was highly embarrassing to a government that made utility privatization one of its key policy objectives. The government approached the Confederation of British Industry to investigate the matter. It subsequently appointed Sir Richard Greenbury, Chairperson and CEO of Marks and Spencer, to investigate and produce a report and recommendations.

The terms of reference of the *Study Group on Directors' Remuneration* (hereafter called the "Group") were "to identify good practice in determining directors' remuneration and prepare a code of such practice for use by UK PLCs" (Greenbury 1995, p. 9). Directors and boards of large PLCs were the focus of the Group though the *Greenbury Report* highlighted that the principles also applied to smaller listed corporations and to other senior executives. The aim of the Group was not necessarily to reduce executive pay, rather to provide a means of establishing a balance between executives' pay and their performance and enhancing accountability and transparency on executives' pay. The final *Greenbury Report* was produced in 1995 and focused on providing recommendations in four main areas, including:

- Remuneration committees
- Remuneration policy for executive and non-executive directors
- Service contracts and compensation on termination
- Disclosure

These are now discussed in turn.

Remuneration Committees

The *Greenbury Report* recommends all PLCs establish a remuneration committee as a subcommittee of the board and that it be assigned full responsibility for all matters relating to executive pay. Where this is not done, the board must explain why and outline the alternative arrangements which have been put in place in the annual report. The intention for the creation of remuneration committees was to prevent executives from designing their own pay packages.

The *Greenbury Report* recommends that the remuneration committee: has a clearly defined terms of reference that ensures there is a corporation-wide policy on remuneration; determines individual remuneration packages for each executive; and reports directly to shareholders on all matters relating to executive remuneration. The *Greenbury Report* recommends that membership

of the remuneration committee should comprise only non-executive directors as they have no direct personal financial interest in executive remuneration. In addition, membership is not to include directors with other executive directorships, as this could result in the bidding up of one another's remuneration. The remuneration committee members are to have a good knowledge of the corporate and its executive directors and a full understanding of shareholder concerns. As a result, Greenbury rejected proposals that the remuneration committee include independent members from outside of the corporation as they would lack the recommended level of knowledge. However, this was deemed to be a weakness as a way around this could have been included, such as ensuring that appropriate training or access to relevant expert advice is provided to the remuneration committee. The *Greenbury Report* recommends that a minimum of three directors make up membership of the remuneration committee in large corporations. Finally, the report recommends that the fees of non-executive directors, some of whom will be members of the remuneration committee, are determined by the whole board.

Remuneration Policy

The underlying basis for the remuneration policy outlined in the *Greenbury Report* is that executive remuneration should be sufficient to attract and retain the appropriate executive talent though avoiding paying more than is necessary for this purpose. To determine the appropriate remuneration, the *Greenbury Report* recommends the remuneration committee identify an appropriate comparator group of corporations and investigate how performance and remuneration are linked in those corporations and how pay is divided between the various fixed elements, such as basic salary, benefits in kind, and variable elements, such as annual bonus and long-term incentives. The *Greenbury Report* identifies a role for both annual bonuses and long-term incentive schemes to encourage and reward executive performance. It is recognized that the mix of rewards

based on short-term and long-term indicators will vary between corporations and are established by the remuneration committee; however, the *Greenbury Report* does emphasize that bonuses are based on financial or operational measures that are "relevant, stretching and designed to enhance the business" (*The Greenbury Report*, 1995, p. 39). Similarly, the report recommends that long-term incentive schemes, including share option schemes, are payable only where stringent performance criteria are met, criteria that measure some aspect of the corporate's performance. Bonuses paid partly in the form of shares should be held for a minimum period of time, to create a long-term focus for the executives and to align their interests more closely with shareholders. A well-designed scheme should ensure that any "windfall gains" are aligned with actual improvements in corporate performance. Finally, the *Greenbury Report* highlights that performance targets need not be restricted to financial measures. They can include "operational" measures of performance, for example, quality or customer service. This recognition of nonfinancial performance measures enables remuneration committees to include sustainability targets such as reducing emissions in performance-based remuneration packages.

For non-executive directors, the *Greenbury Report* recommends fixed fees based on time required for the role. It also counsels against setting remuneration that is linked to performance. It is argued that a fixed fee structure is more likely to maintain independence. This indicates a stewardship view of the role of non-executive directors and contrasts with the stance taken in the *Greenbury Report* for executive remuneration which is firmly set in an agency framework.

Service Contracts

The *Greenbury Report* recommends that director service contracts are on a 1-year basis, to avoid large termination payments due to early termination of 3- to 5-year contracts. Payments for contract termination are not to be included in employment contracts and, should be negotiated

if the situation arises and reflect the reasons for the termination. Poor performance is not rewarded with a generous exit package, and compensation payments should be phased, rather than awarded as a lump-sum. These payments should cease when the director secures new employment.

Disclosure

To improve accountability and transparency on remuneration, the *Greenbury Report* requires full disclosure of information on all aspects of executive remuneration. The primary method of disclosure is the *Report of the Remuneration Committee* included in a company's annual report. The remuneration committee report will outline the corporate's general policy toward executive remuneration and provide detailed information on the actual remuneration packages of the individual executives and the breakdown per executive of the elements of the packages. The remuneration committee report should also outline the measures of performance used to determine rewards, how these relate to the long-term corporate objectives, and how rewards are linked to the measures themselves. In addition, details on the composition of the comparator groups and how they have performed are to be included.

To further align shareholder and executive interests, the *Greenbury Report* recommends that corporations seek a non-binding, advisory vote from shareholders on long-term incentive schemes. However, the *Greenbury Report* did not recommend a vote on the remuneration committee report or the full executive pay details.

Criticism of the Greenbury Report

The Confederation of British Industry, the Institute of Directors, and political opposition criticized the *Greenbury Report* and commented that it had not gone far enough in regulating business behavior (Jones and Pollitt 2002, p. 21). The main criticisms of the *Greenbury Report* are now outlined in brief.

It was claimed that a weakness underlying the *Greenbury Report* was that it was a reactive report,

commissioned in response to public criticisms of remuneration packages enjoyed by executives in recently privatized utility corporations. Yet despite being commissioned in response to the behavior of executives in setting their own pay in utility corporations, interim reports did not address utility corporations, although this was rectified in the final report (Jones and Pollitt 2002).

It was argued that the *Greenbury Report* promoted a tick-box approach to good governance and executive remuneration. It enabled corporations, considered to have "excessive" executive compensation packages, to claim best practice by complying with the recommendations in the *Greenbury Report*. For example, British Gas, one of the corporations whose behavior led to the commissioning of the report, claimed it was at the leading edge of best practice simply because it disclosed its policies (Jones and Pollitt 2002, p. 21)!

Weaknesses were also documented in respect of its recommendations. The focus on the "knowledge of the corporation" as the basis for excluding external members from the remuneration committee implicitly excludes newly appointed directors, yet newly appointed directors are arguably the most independent. Thus, there is an implicit trade-off between director independence and knowledge of the corporation. This conflict could have been eliminated had the *Greenbury Report* recommended that the remuneration committee seek counsel from external expert advisors and external consultants. New directors would not be eliminated from being members of the remuneration committee as they could gain advice from these experts when required. The inclusion of external remuneration advisors was later recognized in the revised Combined Code 2003, and the use of external experts is now a common practice. There is no guidance on how remuneration committees can deal with potential challenges and conflicts in the *Greenbury Report*.

It was argued that the *Greenbury Report* and working group were self-serving, consisting mostly of executives who benefitted from the status quo and were unlikely to recommend any radical new proposals (Jones and Pollitt 2002; Price 2016). The Group lacked representation from and engagement with other stakeholders,

such as small shareholders, employees, customers, and the media whose voices led to the creation of the Group (Jones and Pollitt 2002, pp. 19–20). For example, the *Greenbury Report* required that the remuneration committee have an “understanding of shareholder concerns”; however, shareholders had limited involvement with the working group that was established to review executive remuneration, and specific procedures for gaining an understanding of shareholder concerns were not included. The Group defended their decision not to include measures such as “say-on-pay” in the *Greenbury Report* as shareholders already had opportunities to raise their concerns at corporate annual general meetings (*The Greenbury Report*, 1995, pp. 32–33). However, the Group failed to consider the rights of small shareholders whom had demonstrated outside the British Gas annual general meeting as they did not feel listened to by the board or by the large institutional shareholders. This failure to consider shareholder views on executive pay was tackled by legislators in 2002, when UK corporate law introduced a requirement that corporates conduct an advisory “say-on-pay” at the annual general meeting (Petrin 2015).

It was argued that the publication of pay and benchmarking remuneration policy against comparator corporates could have had an inflationary effect on executive pay (Hughes 1996). With respect to benchmarking, there was limited guidance on what corporates should be included in the comparator group, leaving it open to manipulation by unscrupulous executives.

There were no financial incentives provided in the *Greenbury Report* for non-executive directors, yet non-executive directors would comprise the remuneration committee and set the remuneration policy. Further, it was noted that the recommendation for flat fees for non-executive roles was not supported by evidence (Hahn 2006; Hahn and Lasfer 2010). Indeed, it was claimed that flat fees could have negative consequences as they could relieve non-executives from the burden of responsibility for financial loss as a result of their errors. Moreover, Hahn (2007) reported no association between attendance at meetings and non-executive director fees and concluded that flat fees do not encourage effort.

Despite these weaknesses, there was a significant improvement in the quality and quantity of disclosures relating to directors and executive remuneration following the *Greenbury Report*. However, it is claimed that the increased disclosure and transparency did not translate into the desired results, as remuneration disclosure often lacked clarity on the relationship between performance and rewards (Petrin 2015). In addition, most remuneration committees were not independent, and few corporations gave their shareholders a vote on pay, despite shareholder concerns about executive compensation (Petrin 2015).

Summary

Prior to the *Greenbury Report*, the absence of reporting requirements on remuneration committees resulted in opaque remuneration decisions that were difficult to challenge. The *Greenbury Report* and subsequent measures, that target the pay-setting process, have demonstrated that governance can improve the regulation of executive pay. In addition, it is claimed that the links between pay and performance have improved (Petrin 2015; Ndzi 2016). The *Greenbury Report* also introduced the option of nonfinancial performance measures which most corporations now include in the determination of executive pay. Indeed, several studies have found an increasing use of sustainability targets in executive incentive schemes (Abdelmotaal and Abdel-Kader 2016; Clarke 2013; Labini et al. 2019). Thus, investors can identify corporates committed to the long-term interests of shareholders and society by assessing their remuneration policies.

However, despite the improvements in transparency and accountability, the 2008 global financial crisis revealed it was still possible for executives to receive immense salaries and bonuses while running up toxic debts and unsustainable levels of risk in the corporations they governed. Thus, shareholders continued to be exposed to unacceptable levels of risk associated with excessive executive pay. Moreover, it is now evident that corporate failure does not only impact on shareholder wealth. The economic fallout in the aftermath of the financial crisis verified

how important the financial industry and corporate success is to society at large.

The principle established in the *Greenbury Report*, that corporate boards are best suited to determine their directors' remuneration, still stands. However, leaving executive pay to boards, the continued existence of gray areas and a lack of enforcement procedures tends to lead to ever-increasing executive pay and the associated risks not only to shareholders but to society.

Definition

The greenhouse effect is the natural process of warming of the earth surface. When infrared radiations from the sun reaches the earth, some of these radiations are reflected back into space while the rest is absorbed and re-radiated by atmospheric gases called greenhouse gases (see Fig. 1). This phenomenon is generally referred to as the greenhouse effect (Lallanila 2018). Life on earth depends on energy from the sun and about 30% of the sunlight that beams toward earth is deflected by the outer atmosphere and scattered back into the space. The remaining 70% reaches the earth's surface and is reflected back again as a type of slow-moving energy called infrared radiation (Khan 2017); the heat produced as a result of this infrared radiation is naturally trapped by the greenhouse gases (GHGs) – carbon dioxide, methane gas, water vapor, etc., thereby keeping the earth warm enough for living organisms to survive. However, in recent times and due to overwhelming effects of global civilization and industrialization, human activities have led to surge in the concentration of these GHGs in the atmosphere, in excess of their threshold concentrations, thereby leading to rise in temperature and warming of the planet earth – otherwise known

as global warming. This human-induced greenhouse effect has also resulted into significant changes in the climatic conditions of the different regions of the world. The temperate region of the world is characterized with a rise in sea level, frequent flooding, hurricanes, and tornadoes, while the tropical region experiences incremental rise in temperature leading to a drastic fall in sea level, water scarcity, more famines, and spread of diseases (Olaoye et al. 2017). According to information provided by the Intergovernmental Panel on Climate Change (IPCC), the increase of anthropogenic GHGs emission have been greatly intensified by human activities, such as burning of fossil fuels, industrialization, deforestation, and land degradation (IPCC 2018).

Introduction

The famous Swedish chemist Svante Arrhenius has coined the term “greenhouse effect” at the turn of the century and it simply implies the capture of heat from the atmosphere by greenhouse gases such as water vapor, methane, and carbon dioxide; these gases are naturally present in the earth's atmosphere (Gedzelman 2016). The greenhouse effect can either be natural or human-induced; the natural greenhouse effect takes place due to the presence of naturally occurring greenhouse gases which help to keep the earth at a temperature that is suitable for survival. This phenomenon is equally important in pulling the average global temperature up; without the effect of this natural greenhouse gases, the average earth's temperature would have been -18°C which is far below freezing temperature of water. On the contrary, the induced greenhouse effect is as a result of the increase in concentration of these greenhouse gases beyond their respective threshold values within the planet earth; this is most times due to the imbalances between carbon source (emission of gases from human activities and natural systems) and carbon sink (removal of greenhouse gases from the atmosphere) (Lallanila 2018; Khan 2017).

Since the industrial revolution, human activities such as the burning of fossil fuels (coal, oil, and

Greenhouse Effect, Fig. 1 The greenhouse effect. (Source: Encyclopædia Britannica 2020)

natural gas) have caused the release of tremendous amount of CO₂ into the atmosphere; however, forests which have served the earth as carbon sink has been overly degraded leading to the buildup of carbon concentration in the atmosphere and capture of excess heat – global warming. This human-induced greenhouse effect is likely to significantly alter the global climate, with serious consequences for the human survival especially in the developing countries (Matemilola et al. 2019a). Arrhenius had estimated in the nineteenth century that if burning fossil fuels caused atmospheric CO₂ levels to double, global temperatures could rise by 5 °C. Similarly, it has been estimated that the average global surface temperature could be about 1–2 °C higher than the current temperature (Gedzelman 2016).

Carbon dioxide appears to be the most common greenhouse gas; however, several other gases emitted by human activities also have greenhouse effects such as methane (CH₄), water vapor (H₂O), chlorofluorocarbons (CFC), nitrous oxide (N₂O), ozone (O₃), and carbon tetrachloride (Ramanathan et al. 1985). Though the most abundant gases in the atmosphere are nitrogen and oxygen, these are diatomic compounds and do not contribute to the greenhouse effect. Methane is estimated to be 21 times more powerful than carbon dioxide with an atmospheric lifespan of approximately 12 years. Nitrogen oxide is 310 times more potent as a greenhouse gas than carbon dioxide and has an atmospheric life span of 120 years. It is also important to note that methane and carbon dioxide are widely emitted when burning fossil fuels and that nitrogen oxide is generated during agricultural activities as well as when burning solid waste, while gaseous fluorides mainly come from industrial activities (National Research Council 2001; Olaniyi et al. 2014; Ramanathan et al. (1985).

Impact of Greenhouse Effect on the Environment

Global Warming

Increasing the concentration of greenhouse gases decreases the outgoing infrared radiation and as a result of this anomaly, the earth's climate changes

to restore the balance between incoming and outgoing radiation (EPA 2017). To achieve this balance, the excess heat warms up the earth's surface and the lower atmospheres thereby leading to an increase in the average temperature of the planet earth. This temperature increase causes faster evaporation on land. Many dry areas, including the western part of America, Southern Africa, India, and Australia, are experiencing more severe droughts. The amount of land on the earth suffering from drought conditions has doubled since 1970. This has occurred even as total global rainfall has increased by an estimated 10% (Khan 2017; Matemilola et al. 2019a). Furthermore, Latake et al. (2015) reported that global average surface temperature is likely to increase by 1.4 °C to 5.8 °C by the end of 2100. This projection takes into account the effects of aerosols which tend to cool the climate as well as the delaying effects of the oceans which have a large thermal capacity. However, there are many uncertainties associated with this projection such as future emission rates of greenhouse gases, climate feedbacks, and the size of the ocean delay (Latake et al. 2015).

Sea Level Rise

The impacts associated with human-induced greenhouse effect are directly and indirectly linked. For example, if global warming continues as a result of increase in the earth's average temperature, the sea level will continue to rise due to two different phenomena – melting of from polar sheet/mountain glaciers and thermal expansion of sea water (Latake et al. 2015; Warrick and Farmer 1990). Latake et al. (2015) affirmed the prediction that the earth's average sea level will likely rise by 0.09–0.88 m between 1990 and 2100.

Potential Impact on Human Life

A measurable rise in sea level will have a serious economic impact on low coastal areas and islands, for example, increasing the rates of beach erosion along the coasts and increasing sea level by squeezing fresh groundwater for a considerable interior distance (EPA 2017; Karl and Trenberth 2003). The effect of global warming can affect the general circulation of the atmosphere and thus modify the pattern of global precipitation as well

as the soil water content on several continents. The loss of coastal wetlands could certainly reduce fish populations, especially crustaceans. While global precipitation is expected to increase, it is unclear how regional rainfall patterns will change. In some areas, there may be more precipitation, while in others, there may be less. In addition, higher temperatures would likely increase evaporation. These changes would likely create new tensions for many water management systems (Latake et al. 2015).

Summary

Greenhouse effect occurs due to the presence of water vapor, carbon dioxide, methane, and some other gases, referred to as greenhouse gases in the earth's atmosphere. Of these greenhouse gases, water vapor is the most potent and is responsible for about 60% of the total greenhouse effect, while carbon dioxide is the most abundant and the standard for measuring the global warming potential (GWP) of all other gases. Greenhouse effect occurs naturally but can also be induced by human activities mostly due to the burning of fossil fuels such as coal, oil, and gas.

Carbon emissions; GHG emissions

Definition

Greenhouse gases (GHGs) are those gases in the atmosphere that trap the heat of the sun and make the Earth warmer. This heat trapping property of GHGs is known as greenhouse effect. Greenhouse effect occurs naturally in the atmosphere and is essential to keep the planet warmer for the survival of living beings. The relentless march toward development and industrialization since the time of Industrial Revolution has led to unprecedented increase in GHG emissions in the atmosphere accelerating this greenhouse effect and resulting in rise in Earth's surface temperature. Global warming and the resultant climate change caused by an abundance of GHGs in the atmosphere have become one of the most serious global threats today causing health, ecological, and survival crisis. Their existing and potential impacts include glacier retreat, decline in Arctic sea ice, increasing sea levels, extreme weather conditions, changing crop growth, and altered rainfall and snow patterns. International mechanisms such as IPCC (1988), UNFCCC (1992), Kyoto Protocol (1997), and Paris Agreement (2015) are combined international efforts convened by the United Nations aiming to deal with the situation.

Introduction

"Greenhouse gases are those gaseous constituents of the atmosphere, both natural and anthropogenic, that absorb and emit radiation at specific

wavelengths within the spectrum of terrestrial radiations emitted by the Earth's surface, the atmosphere itself and by clouds. This property causes greenhouse effect" (IPCC 2018). This greenhouse effect keeps the Earth warmer without which the Earth would have been too cold to be suitable for living systems. In the past few decades, the burning of fossil fuels in various industrial processes, electricity generation and transportation, extensive clearing of forests for residential and industrial buildings, and other development activities have led to significant increase in the emission of GHGs. The abundance of GHGs in the atmosphere has caused an increase in average global temperature on the Earth leading to substantial climate impacts including the harm to well-being of humans and ecological systems. "Human influence on the climate system is clear, and recent anthropogenic emissions of greenhouse gases are the highest in history. Recent climate changes have had widespread impacts on human and natural systems" (IPCC 2014b). In the present scenario, it has become inevitable that various countries should work together for international action on adaptation and mitigation so as to reduce GHG emissions and combat climate change.

Main GHGs in the Atmosphere

"Water Vapour (H_2O), carbon dioxide (CO_2), nitrous oxide (N_2O), methane (CH_4) and ozone (O_3) are the primary GHGs in the Earth's atmosphere" (IPCC 2018). Other important GHGs in the atmosphere are "Hydrofluorocarbons (HFCs), perfluorocarbons (PFCs) and sulphur hexafluoride (SF₆)" (UNEP 2018). These gases are found in lesser quantities but have high global warming potential. The amount of GHG emissions in the atmosphere due to human activities is constantly increasing. In order to control the unprecedented rise in GHG emissions in the postindustrialization period, parties to UNFCCC entered into an agreement at Kyoto, Japan, in 1997, known as Kyoto Protocol. The Protocol set the binding obligations for developed nations to reduce

GHG emissions. During its first commitment period (2008–2012), Kyoto Protocol covered emission of six main GHGs namely, “Carbon Dioxide (CO₂), Methane (CH₄), Nitrous Oxide (N₂O), Hydrofluorocarbons (HFCs), Perfluorocarbons (PFCs) and Sulfur Hexafluoride (SF₆)” (UNFCCC 2020a).

Thus, the key GHGs emitted by human activities are the following:

- Carbon dioxide (CO₂) – Emissions of CO₂ naturally occur in the atmosphere as part of the carbon cycle through animal and human respiration, ocean and other atmospheric changes. The burning of fossil fuels for different human activities is the main source of CO₂. A number of industrial processes (such as chemical process, cement production), commercial activities (such as heating), or residential activities (such as cooking, electricity use, and waste disposal) lead to emission of CO₂ in the atmosphere. Deforestation, clearing of land for agriculture and other uses, and degradation of soil also cause increased concentration of CO₂ in the environment.
- Methane (CH₄) – Methane is also a substantial component of the natural gases and is related with all hydrocarbon fuels. Emissions of methane are also associated with agricultural activities, animal husbandry, waste management, energy use, and biomass burning.
- Nitrous oxide (N₂O) – N₂O is released naturally from a number of biological sources in soil, water, and forests. Significant amounts of N₂O emissions also take place during agricultural activities, waste water treatment, combustion of fossil fuel, fertilizer utilization, and chemical processes in the industry.
- Fluorinated gases (F-gases) – F-gases include hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), and sulfur hexafluoride (SF₆). These result from a variety of industrial and manufacturing processes, refrigerants, and other human activities. F-gases are emitted in smaller quantities than the other GHGs, but they have high potency and lifespan in the atmosphere and are often referred to as high global warming potential (GWP) gases.

Though there are many GHGs in the atmosphere, Carbon dioxide is the main GHG accounting for more than three-fourth of total GHGs (Olivier et al. (2017)). According to IPCC report on climate change, “CO₂ emissions from fossil fuel combustion and industrial processes contributed about 78% to the total GHG emissions increase from 1970 to 2010, with similar percentage contribution for the period 2000–2010” (IPCC 2014a). Therefore, GHG emissions are usually measured in terms of their carbon dioxide equivalent. “In order to convert emissions of a GHG into CO₂ equivalent, these emissions are multiplied by the GHG’s Global warming potential (GWP)” (US, EPA 2019a). Each GHG’s effect on global warming (GWP) depends upon its concentration in the atmosphere, its life in the atmosphere, and the intensity with which it can impact the warming of the planet.

Sources of GHG Emissions

“GHG emissions can also be categorized into Biogenic and anthropogenic types” (IPCC 2018). While biogenic emissions are caused by natural biological processes like decomposition of vegetative matter, human activities such as burning of fossil fuels, deforestation, etc. lead to anthropogenic emissions. The primary sources of anthropogenic GHG emissions are the following (US, EPA 2019b), Olivier et al. (2017):

1. Transportation: This sector includes movement of people and goods through various means of transport. Burning of fossil fuels (mainly petroleum-based fuels) for running cars, airplanes, ships, etc. is one of the main sources of GHG emissions. GHG emissions from combustion of petroleum-based products result in emission of mainly CO₂. Small amounts of methane and other gases are also emitted during fuel combustion.
2. Electricity generation: Electricity generation involves burning of fossil fuels such as coal and natural gas leading to the emission of a lot of CO₂ and a smaller amount of other GHGs. Some GHG emissions take place during

transmission and distribution of electricity. At the time of electricity end-use also, some emissions take place.

3. Industrial and mining activities: Various industrial activities require burning of fossil fuels for energy which leads to GHG emissions. In addition, chemical processes used in industry and leaks from various processes also contribute to GHG emissions.
4. Commercial and residential activities: Different commercial and industrial activities such as heating, cooking, waste management, and disposal lead to the release of GHGs. Leaks from air conditioners and refrigerators are also a source of GHG. Waste water management contributes to methane and NO₂ release.
5. Agricultural activities: GHG release from this sector comes from livestock, crop production, and other activities. Livestock produce a large amount of methane when digesting food. Manure from livestock also contributes to methane and NO₂ emissions.
6. Land use and forestry: Forests help in regulating the climate by absorbing CO₂ from the atmosphere (sinks). Due to massive deforestation and altered land use, this positive effect is lost. In addition, when trees are cut, the carbon stored in them is released leading to high concentrations of CO₂ in the atmosphere.

Thus, human activities are affecting the natural carbon cycle both ways. On the one hand, activities such as burning of fossil fuels or various agricultural and industrial activities are adding more and more GHGs in the atmosphere; on the other hand, deforestation and altered land use are affecting the capacity of natural sinks to absorb CO₂ from the atmosphere.

According to US EPA, in 2017, main sources of GHG emissions in the USA included the following:

Source	Percentage of total GHG emissions in USA in 2017 (%)
Transportation	28.9
Electricity production	27.5
Industry	22.2

(continued)

Source	Percentage of total GHG emissions in USA in 2017 (%)
Commercial and residential	11.6
Agriculture	9
Land use and forestry	11.1

Source: Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990–2017. Retrieved from US, EPA (2019b)

GHG Emissions by the Economic Sector

GHGs can also be segregated on the basis of economic activities that result in their emissions. According to a report by IPCC, the following were the main sectors responsible for global GHG emissions in 2010:

Economic activity	Percentage of 2010 global GHG emission (%)
Electricity and heat production	25
Industry	21
Agriculture, forestry, and other land use	24
Transportation	14
Buildings	6
Other energy	10

Source: IPCC (2014b). Retrieved from US, EPA (2019c)

“Since 1970, CO₂ emissions have increased by about 90%. Seventy-eight percent of the total GHG emission increase from 1970 to 2011 has resulted from combustion of fossil fuels and other industrial processes. Agriculture, deforestation and other land use changes have been second largest contributors” (IPCC 2014b).

Global GHG Emissions by Country

According to UNEP (2018), “the top four emitters of GHGs are China, the USA, EU28, and India. These together contributed to 56% of total GHG emissions over the last decade. In 2017, while China was responsible for 27% of total global GHG emissions, EU’s share in the global GHG emissions was 9% and the USA accounted for

13% of total global emissions. Due to its huge population, India's share in GHG emissions was 7.1%, though its per capita emissions were low". "While the top 3 emitters (China, the EU and USA) together- accounted for about half of the total GHG emissions, the bottom 100 countries contributed only 3.5%" (Friedrich et al. 2017).

Combating Climate Change: Mitigation and Adaptation

Climate change is one of the major global problems today. To deal with this problem, an urgent need was felt for policies at regional, national, and international levels. Since the late 1980s, the United Nations is making concerted efforts to bring together different countries in dealing with the problems caused by GHG emissions, global warming, and the resultant climate change. IPCC (1988), UNFCCC (1992), Kyoto Protocol (1997), and Paris Agreement (2015) are some of the combined efforts led by the United Nations which indicate increasing mitigation potential and suggest cost-efficient mitigation measures. In 2015, countries reached a landmark agreement at Paris with the main aim of strengthening the global responsibility to deal with the threat of climate change. The Paris agreement set the target of "keeping the global temperature rise in this century well below 2 °C above the pre-industrial levels and to pursue efforts to limit the temperature further to 1.5 °C" (UNFCCC 2020b). In order to achieve the targets set in the Paris Agreement, countries are required to strengthen their Nationally Determined Contributions (NDCs) and enhance the effectiveness of their domestic climate policies.

Adaptation and mitigation are the two important approaches to deal with GHG emission-related climate change at international level. "Adaptation and mitigation are complementary strategies for reducing and managing the risks of climate change" (IPCC 2014b). Mitigation, in this context, refers to human efforts to reduce the sources of GHGs or to increase the sinks that can absorb them (UNEP 2018).

Various mitigation measures include the following:

- Efficient utilization of fossil fuels during industrial processes, transportation, and electricity generation
- Fuel switching to less carbon-intensive non-fossil fuels such as hydroelectricity, bio-fuels, etc.
- Use of renewable energy sources, such as wind and solar energies which are almost nonemitting
- Conservation of energy at different points mainly at end use
- More efficient use of fossil fuels in electricity generation
- Carbon capturing as a by-product before it enters the atmosphere and its sequestration
- Improving fuel efficiency in transport or machines with advanced design, material, and technology
- Improving operating practices such as regular maintenance of machines, vehicles, etc.
- Reducing travel demand through measures such as work from home, online conferences, etc.
- Recycling
- Training and awareness of employees and public on energy conservation and less emitting practices
- Waste and waste water management
- Reducing leakages from ACs and refrigerators
- Land and crop management such as manure management, livestock management, etc.
- Afforestation to increase sinks to absorb CO₂ from the atmosphere

Summary

Global warming caused by an abundance of GHGs in the atmosphere is leading to unwanted changes in the climate. It has been widely recognized that climate change is one of the most serious challenges faced by the world today endangering the health and survival of living beings on the Earth. "Continued emission of GHGs will cause further warming and long-

lasting changes in all components of the climate system, increasing the likelihood of severe, pervasive and irreversible impacts for people and eco-systems. Limiting climate change would require substantial and sustained reductions in GHGs which, together with adaptations, can limit climate change risks” (IPCC 2014b). Since GHG emissions are mainly caused by burning of fossil fuels, a shift from fossil fuels to nonfossil fuels and renewable energy sources should be the top agenda of various governments. In addition, other mitigation measures such as conservation of energy and water, sustainable transportation, green building, cleaner fuels, sustainable agriculture and industrial activities, reforestation, responsible consumption, and recycling are also required to reduce GHG emissions in the atmosphere. An urgent need is there to reduce the dependence of economic, industrial, and developmental activities on energy use and the resulting GHG emissions.

Greenhouse Gases

Irmgard Buder

Faculty of Communication and Environment,
Rhine-Waal University of Applied Science,
Kamp-Lintfort, Germany

Synonyms

GHG

Definition/Description

Greenhouse gases (GHG) are gases which are able to absorb and to emit infrared radiation. Most of

the incoming solar radiation is let in by GHG heating up earth's surface. The heat is emitted from earth's surface as infrared radiation, which is partly absorbed by GHG and thus prevented to escape to space (Ma 1998). This trapping of heat energy is named Greenhouse Effect (see ► [“Greenhouse Effect”](#)). By increasing the amount of atmospheric GHG, as for example water vapor, carbon dioxide, methane, nitrous oxides, and chlorofluorocarbons, which absorb infrared radiation, global temperatures increased within the last century already by around 1 °C (Lindsey and Dahlman 2018) (see ► [“Climate Change”](#)).

Introduction

Gases, which absorb and emit infrared radiation, are named greenhouse gases (GHG) in analogy to a greenhouse. In greenhouses glass plates are permeable for radiation in the visible range (400–800 nm wavelength). Part of the visible radiation is absorbed and transformed into infrared radiation, which cannot permeate through the glass plate, so it is trapped and the interior of the greenhouse is heated up.

Like glass plates, GHG are permeable for incoming solar radiation energy, which is partly absorbed on earth's surface and transformed into infrared radiation (IR). IR is partly directly emitted into space, partly absorbed by GHG. GHG emit part of the absorbed IR radiation back to the surface, which is heated up by the additional radiation (see ► [Greenhouse Effect](#)). Without greenhouse gases, most important water vapor, earth would have a temperature of around −18° instead of around +15 °C (Ma 1998). Naturally occurring greenhouse gases are water vapor, carbon dioxide, methane, nitrous oxide, and ozone (Kondratyev and Varotsos 1996; Montzka et al. 2011). Due to human influence, the proportion of these gases in the atmosphere increased. In addition, non-natural GHG were emitted, which is causing global warming (Montzka et al. 2011). The effect of GHG to global warming depends on the ability to adsorb IR radiation and the life time of the GHG in atmosphere (Myhre et al. 2013).

Since CO₂ is the most important GHG, the global warming potential of other greenhouse gases is usually given in carbon dioxide equivalents (CO_{2e}), means the equivalent of the global warming potential of CO₂ (see ► [“Carbon Emissions,”](#) ► [“Greenhouse Gas Emissions,”](#) ► [“Climate Change”](#)). As unit usually kilogram or metric ton (t) is used (Krey et al. 2014).

Regulations of GHG Emission

In 2015 in Paris a worldwide agreement was achieved, that temperature change should be kept below 2 °C. Additional actions should be taken to keep temperature increase below 1.5 °C (UNFCCC 2015) (see also ► [“Climate Change”](#)). This agreement was preceded by the Montreal protocol 1989 (Heath 2017), which regulated the emission of gases with depletion potential of ozone in the stratosphere (ODS), and the Kyoto protocol (UNFCCC n.d.). In the first period of the Kyoto Protocol, the emission reduction targets for carbon dioxide (CO₂), methane (CH₄), nitrous oxide (N₂O), hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), and sulfur hexafluoride (SF₆) were defined (UNFCCC n.d.). In the Doha amendment, nitrogen trifluoride was added to the list of GHG (UNFCCC 2013).

GHG Regulated by the Kyoto Protocol

Carbon Dioxide

Carbon dioxide CO₂ is occurring naturally as part of the biological and geological carbon cycle (Sundquist 1985). Additional CO₂ is released by human activities, most important combustion of fossil fuels (IEA 2016) (see ► [“Carbon Emissions”](#)). CO₂ has also several applications in industry: In chemical processes, for example, urea production, CO₂ is used as raw material (Behr 1987). CO₂ enriched atmosphere is used in food packaging for increasing conservation of fruits, meat, and other perishables. In fire extinguishers, CO₂ can be applied for class A and B fires (Skaggs 1998). Also the use of CO₂ as

nonflammable refrigerant is discussed (Tsamos et al. 2017) for replacing flammable refrigerants or refrigerants with higher global warming potential as fluorocarbons and hydrofluorocarbons. Nevertheless CO₂ emission caused by industrial applications of CO₂ is up to now negligible compared to the CO₂ emissions caused by burning fossil fuels, steel, and cement production (see ► “Carbon Emissions”).

Methane

Methane CH₄ is occurring naturally as product of anaerobic microbial processes (Schubert 2011) or by “*thermogenic degradation of organic matter in sedimentary rocks*” forming “*the major commercial natural gas reservoirs*” (Etiope and Sherwood Lollar 2013). Small amounts of CH₄ are formed by natural inorganic chemical reactions (Etiope and Sherwood Lollar 2013).

Montzka et al. estimated that two thirds of present total emissions of CH₄ are caused by human activities, most important agriculture, extraction of fossil fuels, and less important waste treatment (Montzka et al. 2011).

CH₄ is the most important component of natural gas (Oyeneyin 2015), an important fossil fuels, which is expected to overtake coal in 2030 (IEA 2018). World natural gas consumption increased from 2516 MBTU to 3752 MBTU in 2017 (IEA 2018) (since composition of natural gas differs for different production sites natural gas is traded internationally in US \$ in per energy unit, given in million British thermal units (MBTU) (BP 2019)).

CH₄ is also used in chemical processes, for example, for production of hydrogen (Wang 2015), which is applied in refining of oil and fertilizer production.

CH₄ has a lifetime of around 9 years in atmosphere and is oxidized by hydroxyl radicals (OH*) to CO₂. Increasing CH₄ ratios in atmosphere are expected to lead to decreasing hydroxyl radicals, which are consumed in this reaction, which leads to a positive feedback mechanism: The more CH₄ is already in atmosphere the longer is the life time of CH₄ in atmosphere (Montzka et al. 2011). Since ozone forms hydroxyl radicals, increasing ozone amounts in the troposphere would on the

other side lead to decreasing CH₄ shares (Su et al. 2012).

According to emission statistics collected by Janssens-Maenhout et al., methane emissions increased from around 12 Gt CO_{2eq} 1970 to ca. 14 Gt CO_{2eq} in 2012 (Janssens-Maenhout et al. 2017, p. 17), which makes methane the greenhouse gas with second highest impact for global warming (see ► “Greenhouse Gas Emissions,” ► “Climate Change”). The share of CH₄ of the total GHG emissions decreased between 1970, when methane had a share of 27%, to 19% in 2012 (Janssens-Maenhout et al. 2017, p. 9). Reason was the shift of developing countries from agricultural societies (with large share of methane emissions) to industrialized economies with increasing fossil CO₂ emissions (Janssens-Maenhout et al. 2017, p. 9).

Nitrous Oxide

Nitrous oxygen N₂O is part of the natural nitrogen cycle (Hofman and Van Cleemput 2004). Applications of N₂O are in medicine as anesthetic (Banks and Hardman 2005) and as propellant in whipped cream (Igoe 2011). Acetylene is combusted at higher temperature if N₂O is provided as oxidants instead of air, which is used for welding and in atomic absorption spectroscopy (Willis et al. 1968). The property of improving combustion can also be used for engines of racing cars (Germane 1985).

Use of fertilizer increases direct emission of N₂O by increasing the amount of reactive nitrogen (Cofman Anderson and Levine 1986). N₂O is also formed as reaction product of nitrogen oxides, which are emitted by combustion of fossil fuels and chemical processes, for example, production of nitric and adipic acid (Montzka et al. 2011).

Montzka et al. estimated in 2011 that around 40% of all N₂O emissions were caused by anthropogenic activities. Emissions of N₂O increased from around 2 Gt CO_{2eq} (1970) to around 6 GtCO_{2eq} (2012) (Janssens-Maenhout et al. 2017, p. 17), which makes it the third most important GHG. Estimated lifetime of N₂O in atmosphere is around 120 years (UNCC 1995). N₂O is very stable in the troposphere. When transported to the stratosphere, it is destroyed by

photocatalytic reactions (Ussiri and Lal 2013). Since N₂O leads to depletion of ozone in stratosphere, it is discussed that it will be the “dominant ozone depleting substance in the 21st century” (Ravishankara et al. 2009). However, up to now it is not listed as ODS in the Montreal protocol and its amendments.

Hydrogen Fluorinated Carbons (HFCs)

Hydrogen fluorinated carbons HFCs were first regulated by Kyoto protocol. They replaced chlorinated fluorinated carbons (CFCs) and hydrogen chlorinated fluorinated carbons (HCFCs) as GHG with ODS (Kuo 2012, p. 25). Of concern is the long life time of HCFCs and HFCs (see also Table 1). Not all of them, which were produced, have been emitted yet but some of them are stored in “banks” reservoirs of produced but not yet released chemicals. “Most chemicals in banks

will ultimately be emitted unless destroyed” (Montzka et al. 2011). Therefore, it is expected that emissions can rise in future. Montzka et al., for example, estimated that 2005 in the USA only 25% of the halocarbons in the bank were accessible for destruction.

In the Kigali amendment to the Montreal protocol, which entered into force 01.01.2019, a fading out of production and use of HFCs has been decided to take place in three phases: “...a group of developed countries starting HFCs phase-down from 2019. Developing countries will follow with a freeze of HFCs consumption levels in 2024 and with a few countries freezing consumption in 2028” (United Nations Environment 2019).

Sulfur Hexafluoride

Most sulfur hexafluoride SF₆ is used as insulating gas in high voltage applications (Kieffell et al.

Greenhouse Gases, Table 1 GHG regulated by the Kyoto Protocol in the first commitment period

Species	Chemical formula	Lifetime in atmosphere (years)	Global warming potential (time horizon) 20 years	Global warming potential (time horizon) 100 years	Global warming potential (time horizon) 500 years
Carbon dioxide	CO ₂	variable §	1	1	1
Methane	CH ₄	12 ± 3	56	21	6.5
Nitrous oxide	N ₂ O	120	280	310	170

Perfluoropentane	C ₅ F ₁₂	4100	5100	7500	11,000
Perfluorohexane	C ₆ F ₁₄	3200	5000	7400	10,700

Source: UNCC (1995)

2016). Other applications are in medicine (Assi and Gregor 2001) and as tracer gas (Calver et al. 2005). It is assumed to be the GHG with the highest global warming potential (see Table 1). Around 80% of SF₆ emissions are caused by use in high voltage applications (Kieffell et al. 2016), where replacement is difficult. At the moment gas mixtures also containing GHG with lower global warming potential or reduced SF₆ contents are discussed as substitutes (Kieffell et al. 2016).

GHG Controlled by the Doha Amendment: Nitrogen Trifluoride

Nitrogen trifluoride NF₃ is used in *“electronics industry, mainly for equipment cleaning, for the etching of microcircuits, and for manufacturing liquid crystal flat panel displays and thin-film photovoltaic cells”* (Weiss et al. 2008). It replaced perfluorinated carbons and it was assumed to be mostly destroyed in these processes (Arnold et al. 2013). Nevertheless measurements in atmosphere showed an increase of NF₃. Due to high life time, it is a very potent GHG (17,200 higher than CO₂) (Alsema et al. 2007). In 2015 it was added in the list of GHG controlled by international protocols (UNFCCC 2013).

GHG Covered by the Montreal Protocol

Emission of gases, which lead to ODS, are addressed in the Montreal protocol and in following amendments, latest the Kigali amendment (Heath 2017). Since these gases, especially chlorofluorocarbons (CFCs), carbon tetrachloride, methyl chloroform, methyl bromide, and halogen alkanes are also potent GHG with long lifetime, reduction of the emission of these gases led also to a reduction of global warming (Montzka et al. 2011). All these gases have no natural sources and emissions of these substances in atmosphere decreased already since the late 1990s from around 9 Gt CO_{2eq} to around 1 Gt CO_{2eq} (Montzka et al. 2011).

CFCs are nontoxic and nonflammable chemicals, which were used in *“manufacture of*

aerosol sprays, blowing agents for foams and packing materials, as solvents, and as refrigerant” (Elkins 1999). They were primarily replaced by HCFCs, which have a lower ODS and lower lifetime (WMO 2010). Now HCFCs are also controlled by the amendments of the Montreal protocol (Montzka et al. 2011). Other substitutes were hydrofluorocarbons (HFCs) (UNCC 1995).

In contrast to CFCs, HCFCs, and HFCs carbon tetrachloride, methyl chloroform, and methyl bromide, used, for example, as solvents, in fire extinguishers and dry cleaning are also toxic and harmful for environment; therefore, their emission should be strictly avoided (Gestis Stoffdatenbank n.d.).

Not Regulated Greenhouse Gases

Water Vapor

Water vapor is assumed to be the largest contributor to the natural greenhouse effect (UNFCCC 2000; Myhre et al. 2013). Its presence in the atmosphere is not directly affected by human activity, since water vapor caused by irrigation and power plant cooling has negligible impact on the water cycle (Myhre et al. 2013), but is controlled by temperature (UNFCCC 2000). *“For that reason, scientists consider it a feedback agent, rather than a forcing to climate change”* (Myhre et al. 2013).

It is estimated that share of water vapor in atmosphere is in average around 5000 ppm (parts per million) (Blasing 2016). Warmer atmosphere will contain more water vapor, so a positive feedback effect by increasing temperature was expected (Rind et al. 1991) (see ► *“Global Climate Change”*). The role of water vapor in climate models is crucial due to its high impact. Water vapor can reinforce the heat absorption (Ma 1998). On the other hand more water vapor can lead to more cloud formation. Clouds have a positive feedback by trapping outgoing thermal radiation, but they increase also the amount of solar radiation reflected back to space (Ma 1998). A positive feedback of increasing water vapor content predicted by early climate

models has already been confirmed by satellite data 1991 (Rind et al. 1991).

Ozone

Ozone O₃ is in the stratosphere an important trace gas, since it absorbs ultraviolet radiation, which otherwise could cause severe damage to living organisms on the Earth's surface (Kondratyev and Varotsos 1996). The primary natural source for ozone in the troposphere is subsidence of stratospheric ozone (Mann 2019). Anthropogenic air pollution leads also to ozone formation by photocatalytic reaction of pollutants as hydrocarbons and carbon monoxide with nitrogen oxides (Andersson-Sköld and Janhäll 1995). The formation of ozone is increased at temperatures above 32 °C, which will occur more often with increasing global temperature (Knowlton et al. 2004). It is a greenhouse gas with high radiative absorption and short life time (Montzka et al. 2011). Due to its low life time, ozone is not considered as a GHG with long lasting effects but as “*near-term climate forcers*” (NTCFs) as those compounds whose impact on climate occurs primarily within the first decade after their emission” (Myhre et al. 2013). On the other side ozone can form hydroxyl radicals by photocatalytic reaction, which reacts with many GHG (Su et al. 2012; Shindell et al. 2009). Tropospheric ozone is also a major irritant to human health and vegetation (Knox et al. 2012).

Summary

In the Kyoto protocol 1997 (UNFCCC n.d.), the Doha-Amendment (UNFCCC 2013) and the Paris Agreement 2015 (UN 2015) emission reduction targets for GHG were set. Additionally GHG with potential to damage the ozone layer were regulated by the Montreal protocol and its amendments.

Carbon dioxide, methane, and nitrous oxide emitted by anthropogenic activities are mainly responsible for the global temperature increase, which was observed in the last century. Water vapor is also a GHG but its content in atmosphere is controlled by temperature, not directly by

human activities. Increase of water vapor in atmosphere due to higher temperature lead to a positive feedback. These GHG are also emitted by natural processes; nevertheless the emissions by mining and burning fossil fuels, agriculture, and other human activities are causing climate change. Other GHG, as hydrofluorocarbons, sulfur hexafluoride, and nitrogen trifluoride are not formed by natural processes. The amount of their emission is low, but since most of them have long life times, their emission lead to long lasting effects on global climate. Ozone is a short lived GHG with high radiative absorption. Increasing amounts of ozone in the troposphere are caused by pollution. But ozone contributes also to formation of hydroxyl radicals which react with GHG, contributing to destruction of other GHG.

Introduction

There will be a day when birds will fall from the sky, the animals that populate the woods will die, the sea will turn black and the rivers will flow poisoned. That day, men of all races will unite as rainbow warriors to fight against the destruction of the Earth. – Kwakiutl legend

Greenpeace is an environmentalist and pacifist nongovernmental organization (NGO) founded in Vancouver in 1971 by Patrick Moore, Robert Hunter, and Dorothy Stowe. Over the years it has stood out for its anti-war actions against nuclear tests, whaling, trawling, global warming, and environmental pollution. In particular, the

organization's actions have, over time, been in contrast with the policies of unlimited exploitation of natural resources (Weyler 2004).

The History

Greenpeace was born on September 15, 1971, led by Jim Bohlen, Irving Stowe, and Paul Cote and journalists Robert Hunter of the *Vancouver Sun*, Ben Metcalfe of the “Canadian Broadcasting Corporation,” and Bob Cummings of the “Georgia Strait” who sailed from Vancouver on board of an old fishing boat, the Phyllis Cormack renamed Greenpeace, toward Amchitka Arctic island of the USA (Alaska) in order to stop the nuclear tests that were taking place on the island. That first action of the then “Don't Make a Wave Committee”, which seemed to have been unsuccessful, found instead the support of the public opinion that supported the request to stop the nuclear experimentation on the island. The meeting in return with the Kwakiutl Indians who exposed to the crew the prophecy of the “Rainbow Warriors” is still told today as particularly significant for the organization. With the financial and volunteer support, a second “Greenpeace Too” expedition was possible, and after the protests that arose from the nuclear test of November 6, 1971, the USA and Canada decided not to carry out new tests on the island of Amchitka which has since become a nature reserve for birds (Weyler 2004).

In 1972 in the Mururoa atoll, the first action against atomic tests in the French atmosphere was held. The then head of mission, David McTaggart, along with a crew of five embarked on the “Vega” ship and approached the atoll where the nuclear tests were scheduled. Although in a first attempt the test was only delayed, in a second the French boarded the ship and injured David McTaggart. A member of the crew will be providential in managing to photograph the event and make it known throughout the world, forcing France to abandon the atmospheric tests.

In 1975 Greenpeace embarked on its famous battle in contrast to the limitless hunt for whales that were leading cetaceans to extinction.

Greenpeace, in contrast to the IWC (International Whaling Commission), decided to act directly against fishing fleets; in particular, they chose a Soviet ship in the northern Pacific. The activists' rubber dinghies interposed between the cetaceans and the whaling ships to block the trajectory of the harpoons. In 1982 the IWC voted a moratorium against whaling still in force today.

In 1985 the Rainbow Warrior was hit and sunk a few minutes before midnight. His crew had recently completed the "Exodus" operation, in the Rongelap Atoll, which called for the evacuation of the citizens of the island of Mejato as requested by their representatives in the Parliament of the Marshall Islands. There were too many cases of thyroid cancer, leukemia, and fetal malformations in this area, caused by American nuclear tests between 1948 and 1956. Greenpeace photographer Fernando Pereira died in the sinking of the Rainbow Warrior. The responsibility for the incident was attributed to the French secret services, but the French government denied direct involvement. A few months later, however, Defense Minister Charles Hernu decided to resign from his post.

Mission/Objectives/Focus Areas

The mission of the organization is the protection of the environment through the denunciation and the non-violent protest of the crimes against it. Greenpeace seeks to raise awareness among the public having as its main objective a change of course of daily habits and lifestyles to prevent them from leading, as it is happening, to the destruction of nature and our planet.

In particular, Greenpeace seeks to raise awareness about an energy revolution, against climate change in progress, protecting oceans and forests and biodiversity and promoting sustainable agriculture and a sustainable food style.

The investigations carried out by the organization are based on documents and scientific research reports, and for this very rigorous approach, the action has grown in importance.

From the outset, the (economic) independence of the organization was fundamental, since by not

accepting money from governments, political parties, and companies, it bases its work on the thousands of supporters who, with private donations, express their sharing of the idea of environmental protection.

Structure of Governance

Greenpeace has a network of 26 organizations located in 55 countries around the world as well as a coordination body "Greenpeace International" based in Amsterdam.

Greenpeace also has a dense network of volunteers and activists, people of all ages who dedicate their time to campaign development and local promotion of the organization without compensation.

Increasingly important has become over time the support of journalists and photojournalists who document the actions.

To date, around 2.8 million supporters are involved.

The currently active naval fleet consists of:

- Rainbow Warrior III (2011)
- Esperanza (1984)
- Artic Sunrise (1975)
- Beluga II (2004)
- Argus (1977)
- Sirius (1951)

Activities/Major Accomplishments/Contributions

Greenpeace is currently very active in the campaign against climate change that is changing the lives of millions of people and that, if not stopped in time, could lead to further dangers for the life of man and living beings on earth. This is also why it has activated the "Save the Arctic" campaign because the melting of Arctic glaciers is taking place with a decidedly faster speed than could be imagined. The local populations are losing out because the animals they eat begin to disappear, and for this reason, they are increasingly forced to emigrate. At the same time, polar bears, seals, and

walruses are put to the test by retreating ice, and all too often, they are no longer able to survive.

Thus the organization's activity also focused on fossil fuels which caused this climate change with a tough campaign against the major oil producers and drilling and the airgun technique. The case of the 1995 Shell Brent Spar platform went to the record. A group of activists coordinated by Harald Zindler protest trying to get off a helicopter on the platform. Rejected with hydrants, their video will travel around the world raising public opinion against Shell (Jordan 2001).

Greenpeace is committed to defending ecosystems and forests against deforestation and intensive agriculture. His campaign has focused particularly on GMOs, which have always been the subject of an international debate due to the impact they can have on the health of human beings.

The historical campaign is to save whales from intensive hunting, but also against the intensification of fishing with incorrect techniques toward nature, which by not correctly respecting the natural cycle seriously endangers the marine balance.

More recent campaigns are those against intensive farming and disposable plastics.

Greenpeace (NGO) II

Bayram Bilge Sağlam

Maritime Faculty, Dokuz Eylul University, Izmir, Turkey

Definition/Description

Greenpeace is an international nongovernmental organization that is focused on attracting public interest on environmental issues. Greenpeace states its mission as “to protect the planet in all its diversity and promote peace and non-violence” (Greenpeace 1999). The environmental issues that Greenpeace concentrates on cover climate change, use of nuclear power, use of hazardous chemicals, deforestation, ocean and terrestrial ecology, and genetic engineering. Since none of the environmental consequences of these issues are individual concerns of any specific country, Greenpeace carries out its activities worldwide. As one of the most recognized environmental organizations in the globe, Greenpeace maintains its operations in over 55 countries through its coordinating body in Amsterdam and regional offices in 41 countries. Organizational policy of Greenpeace is annually decided on the council that is made up of the representatives from each of the regional offices. The council meetings enable coordination of diverse actions and joint planning of the campaign program and each regional office carries out their campaigns accordingly (Eden 2004).

The organization owes its vast recognition mainly on professionalized campaigning skills that is built on environmental direct-action tactics, ecotage, nonviolent protests, boycotts, lobbying, and research (Obach 2007). Since its establishment, the organization has been in continuous confrontations with powerful industries. Such events organized by Greenpeace target raising the environmental issues to public awareness by attracting the attention of mass media. Greenpeace relies on funding from individual supporters and foundation grants and does not accept any form of financial support from

governments or corporations in order to maintain its independence. Greenpeace is known as one of the pioneering NGOs that employs face-to-face fundraising method where fundraisers recruit new supporters and ask for monthly direct debit donations in public areas (Krebber et al. 2016).

The History and Major Accomplishments

Greenpeace was founded in Vancouver-British Columbia in 1971 by environmental activists with the goal of drawing attention to underground nuclear testing which was being initiated by the US military in Aleutian island of Amchitka. With the earthquake-prone nature of Amchitka, the activists feared the explosions that would occur during nuclear testing would cause devastating consequences for the area which housed endangered wildlife. In order to stop the testing, the activists planned to sail to the area with the vessel they named Greenpeace, green representing their ecological concerns and peace representing their stands against military action. Even though their ship was forced to return by the US navy, upon their arrival the activists found that their first major action ignited a significant public interest and non-negligible compassion for their cause. This effect of the activists' direct action eventually led to the termination of the nuclear testing in Amchitka and the island was later declared a bird sanctuary. After the success, the name of the vessel took off and it became the name of the organization. Later that year, a similar achievement was achieved by the young organization as they stopped atmospheric nuclear weapons testing of the French Navy in its tracks (Greenpeace 1999).

In 1975, Greenpeace went beyond campaigning against nuclear activities and set up *Project Ahab* with the aim of protecting the whales from commercial hunting. Its initial actions under Project Ahab took place in North Pacific against Japanese and Soviet fleets and later with Soviet and Scandinavian fleets in North Atlantic (Balser and Carmin 2002). Step by step, the protests were widened in scope to cover direct actions towards protection of other marine animals (such as seals, dolphins, and sea turtles) and preservation of marine fauna in

general. During these events, Greenpeace documented the commercial hunts which helped raising public concern that later elevated into international protests.

By the 1980s, funding network of Greenpeace grew significantly and the agenda of the organization started to expand accordingly. During these years, Greenpeace aimed at publicizing the environmental issues of energy and toxic waste. In 1985, French Foreign Intelligence Services planted a bomb in *Rainbow Warrior* (a vessel of Greenpeace) which was docked in Port of Auckland and was scheduled to sail to protest against the nuclear test in Moruora. In this attack, a Greenpeace photographer drowned. This tragic event resulted in significant growth of Greenpeace supporters (Eden 2004).

In 1990s, Greenpeace put a significant effort towards raising public awareness on climate change and ozone depletion. It was in the beginning of the 1990s when Greenpeace introduced refrigerators named as "Greenfreeze" which are completely free of ozone depleting and global warming chemicals (Conrad 1995). This new technology that Greenpeace has brought to life had carried the refrigerator industry towards an ecofriendly status and thus became a solid step against the major criticism on Greenpeace that "It does not offer any solution, but constantly criticizing." For this accomplishment which encouraged "green consumerism," Greenpeace was awarded by United Nations Environment Programme (1997). By the 2000s, Greenpeace had become increasingly professionalized and adopted its current structure. This new structure allowed Greenpeace to branch out all around the globe and monitor environmental threats that might otherwise be overlooked. Today, Greenpeace maintains its function as an influential environmentalist organization and keeps environmental concerns as a subject matter.

Summary

Grown from a small radical group, Greenpeace today is considered as one of the most influential environmental NGOs. Greenpeace focuses on the

environmental issues such as climate change, use of nuclear power, use of hazardous chemicals, deforestation, ocean and terrestrial ecology, and genetic engineering. Since its inception, the organization carries out campaigns exposing the environmental abuse by governments and multinational corporations in each of these issues. Actions of the organization stand out especially in terms of their success in attracting media attention and raising public consciousness. Beside the direct actions that Greenpeace is mostly recognized with, the organization employs nonviolent protests, boycotts, lobbying, and research in order to reach its goals. While the professional activists carry out rather dangerous protests, ordinary members are employed for fundraising activities.

[Bluewashing](#); [CSR-washing](#); [Disclosure–performance gap](#); [Green spin](#); [Symbolic corporate environmentalism](#); [Whitewashing](#)

Description

Greenwashing is an “umbrella term” for behaviors that mislead consumers regarding the organization’s environmental performance (Lyon and Montgomery 2015). It describes situation, when there is a mismatch between, what organization communicates, and what it actually does in terms of its environmental responsibility. While companies are the primary greenwashing actors, broad review of literature reveals cases of this practice conducted by governments, politicians, university administrators, research organizations, environmental policy experts, industries, and NGOs (Lyon and Montgomery 2015).

The phenomenon of greenwashing emerged as “CSR’s evil twin” (Jong et al. 2017). Potential benefits of corporate social responsibility (CSR), such as license to operate, increased reputation, consumer purchase intentions, and loyalty or reduced capital costs (Doh et al. 2010; McWilliams and Siegel 2011), provide incentives for organizations to engage in environmental programs, and communicate about them. In regard to their environmental performance and communication, organizations can be divided into four types: (1) vocal green organizations that combine good environmental performance with positive communication about their environmental performance; (2) silent green organizations that do not communicate about their good environmental performance; (3) silent brown organizations that do not communicate about their bad environmental

performance; and (4) greenwashing organizations that positively communicate while actually having bad environmental performance (Delmas and Burbano 2015).

Other related terms used in the literature describing this phenomenon are green spin (Alves 2009), the disclosure–performance gap (Font et al. 2012), symbolic corporate environmentalism (Bowen 2014), bluewashing (washing through the United Nations and Global Compact brand) (Laufer 2003), and CSR-washing (broader term used in relation to social and environmental corporate activities) (Pope and Wæraas 2016).

Greenwashing Typologies

The literature offers several complementary taxonomies for greenwashing that encompasses different misleading behaviors ranging “from slight exaggeration to full fabrication” (Lyon and Montgomery 2015, p. 225). Two basic types include **firm-level greenwashing**, e.g., selective disclosure and **product-level greenwashing** regarding environmental benefits of a particular product or service (Delmas and Burbano 2015).

Parguel et al. (2015) distinguish between **executional and claim greenwashing**. The first is defined as the use of nature-evoking elements (e.g., imagery) in advertisements and other promotional materials that help organization to enhance its eco-friendly image. The latter is understood as the use of textual arguments concerning the product or the company that create a misleading environmental claim. Claim greenwashing can be divided into seven “sins,” as identified by TerraChoice (2010):

1. The sin of the hidden trade-off – when one environmental issue is emphasized at the expense of other more serious concerns
2. The sin of irrelevance – when an environmental issue unrelated to the product is emphasized
3. The sin of lesser of two evils – when an environmental claim about the product might be true but distracts the consumer from greater environmental impact related with the whole product category

4. The sin of fibbing – when environmental claims are a lie
5. The sin of no proof – when environmental claims are not backed up by evidence or third-party certification
6. The sin of vagueness – when a marketing claim is poorly defined or broad that it can get easily misunderstood by the consumer
7. The sin of worshipping false labels – when marketers create a false suggestion or certification-like image to mislead consumers

Lyon and Montgomery (2015) build on and expand previous typologies, basing on a broad conception of greenwash. The authors distinguish seven varieties of this phenomenon:

1. Selective disclosure that would also include legitimization strategies companies use to report “negative aspects” (Hahn and Luelfs 2014)
2. Empty green claims and policies or the so-called “cheap talk”
3. Dubious certifications and labels
4. Co-opted NGO endorsement and cross-sectoral participation
5. Ineffective public voluntary programs, including bluewashing (Laufer 2003)
6. Misleading narrative and discourse
7. Misleading visual imagery

Drivers of Greenwashing

Delmas and Burbano (2015) propose a broad theoretical framework describing the drivers that lead brown organizations to positively communicate their environmental performance. The drivers can be divided into three following levels: external, organizational, and individual.

External Drivers

One of the most important drivers of greenwash is lax and uncertain regulatory environment, which allows firms to mislead stakeholders with low risk of being punished. In this weak regulatory activist group, NGOs and media informally monitor corporate green communication and expose greenwashing practices. However, while public

exposure and greenwashing scandals may lead to reputational damages, they do entail any legal risk, what makes them less effective. Indeed, empirical studies have shown that greenwashing is attenuated by external scrutiny in the form of NGO and regulatory pressures (Kim and Lyon 2015).

Another group of external drivers include market forces. For instance, pressures from consumers and investors regarding environmental performance encourage brown companies to create false eco-image. As argued by Meyer and Rowan (1977) in their study on organization myth and ceremony, companies, for the purpose of attaining legitimacy within their environments, are “prone to construct stories about their actions” (Mizruchi and Fein 1999, p. 656) that correspond to stakeholder expectations, but are decoupled from actual business operation. Additionally, organizations tend to model themselves intentionally or unintentionally (through influence of consultants and employees hired from other companies) on more legitimate or successful competitors (DiMaggio and Powell 1983). Thus, the more companies in the industry invest in environmental programs and positively communicate about it, the more likely it is for brown organizations to greenwash.

Testa et al. (2018) show that although institutional pressures generally strengthen the internalization of proactive environmental practices, the various stakeholders behind these pressures can play different roles (either support the integration of environmental practices or encourage superficial adoption). While pressures of public authorities and activists do not force managers to increase integration of environmental aspects in firm’s operations, shareholders, suppliers, banks, and other financial institutions have a positive influence on the honest corporate environmentalism. Pressures from customers and industrial associations encourage greenwashing.

Organizational Drivers

Potential benefits (increased access to green consumers, socially responsible capital, and legitimacy) and costs (communication costs, as well as costs related with legal actions) of

greenwashing vary with basic firm characteristics. Consumer products firms, large publicly traded companies, and manufacturing firms are more likely to engage in greenwashing. While the first face greater levels of consumer pressure related to environmental concerns than service or business-to-business firms, large, the second face higher pressure from investors, including socially responsible investors than smaller, private firms. Finally, the last, manufacturing firms operating in environmentally and socially sensitive industries (e.g., pharmaceutical, textile, gas and oil, and automotive) can count on higher legitimacy benefits related with environmental communication (Delmas and Burbano 2015). Additionally, growing firms are more likely to engage in greenwashing as they expect an increased interaction with stakeholders in the regulatory arena (Kim and Lyon 2015).

From the cost side, larger firms with well-known brands, especially those in consumer products industries, are most likely to be the target of public scrutiny, what increases potential costs of greenwashing (Delmas and Burbano 2015). Likewise, firms that operate in more environmentally damaging sectors, particularly those in countries where they are more exposed to scrutiny and global norms, are less likely to engage in selective disclosure (Marquis et al. 2015). However, more-profitable firms are more immune to reputational crises and bottom-line shocks. It is also easier for them to handle costs related with fines and litigation (Delmas and Burbano 2015).

Other internal drivers of greenwashing are related with incentive structure, ethical climate, age of the organization, and internal communications systems (Delmas and Burbano 2015). Incentive system that rewards managers for reaching arbitrary financial marketing and PR goals often results in unethical behavior, including greenwashing practices. Greenwashing is more likely to occur among organizations with egoistic rather than principled ethical cultures. Further, greenwashing is also more likely to be prevalent in larger and older firms that are usually characterized by higher organizational inertia. Organizational inertia, understood as the tendency of mature organizations to be resistant to strategic

changes, can explain mismatch between declarations of environment protection and actual implementation of these activities. Finally, low effectiveness of firm internal communication and the lack of interactions between marketing/PR departments and product development, production, and packaging departments can act as a driver of unintentional greenwashing.

Individual-Level Psychological Drivers

Under conditions of uncertainty and limited or imperfect information, cognitive tendencies such as narrow decision framing (e.g., short-term focus), hyperbolic intertemporal discounting (e.g., inconsistency between long-term goals and short-term behavior), and optimistic bias (i.e., tendency to overestimate and underestimate the likelihood of positive and negative events, respectively) may also contribute to greenwashing.

The Consequences of Greenwashing

Greenwashing is cited as having negative effect on consumer, investor, and NGO's confidence in corporate environmental activities, eroding markets for sustainable products, socially responsible investment, and increasing the risks for lawsuits for false and misleading statements (Alves 2009; Delmas and Burbano 2015; Nyilasy et al. 2014). The phenomenon threatens the effectiveness of genuine environmental efforts and the global transition towards sustainable economy (Jong et al. 2017). What is more, greenwashing not only has detrimental consequences for the society, but also, as empirical research shows, does not pay off for the organizations themselves (Berrone et al. 2017).

Results of recent studies indicate that benefits of greenwashing are temporary and are limited to short-term image improvement (Baldassarre and Campo 2016). The literature provides empirical evidence that greenwashing has negative effect on overall performance indicators (Jong et al. 2017). For instance, Walker and Wan (2012) find negative effect of greenwashing on financial performance of top performing Canadian firms in industries with negative impact on environment.

Wu and Shen (2013) investigate motives for corporate social responsibility and relationship between CSR and financial performance in banking industry. The authors identify three motives for banks to invest in CSR: strategic choice, altruism, and greenwash. While the results of the study show that CSR positively associates with financial performance, this relationship is nonexistent for banks practicing greenwashing. Similarly, Du (2015) shows that while corporate environmental performance is significantly positively associated with cumulative abnormal returns around the exposure of misleading practices, for greenwashing this relationship is negative.

Other authors (Berrone et al. 2017) provide evidence that different environmental actions have different impact on environmental legitimacy. The study shows that environmental patents are effective in producing legitimacy, regardless of the company's credibility or the level of normative scrutiny it faces. High visibility and implementation costs of environmental patents make them the strongest signal among the environmental actions studied. Other actions, such as environmental pay policies, environmental board committees, participation in government's environmental program, or environmental trademarks, constituting weak signals, are less likely to be seen authentic. They build legitimacy only when the company has strong credibility. In other circumstances, especially in the presence of vigilant environmental NGOs, they are counterproductive.

The potential benefits and costs of greenwashing for companies have been also traced in experimental studies on the influence that such practices have on consumers. However, the results of this investigation are still inconsistent. On the one hand, Spack et al. (2012) present evidence that although consumers are able to assess the honesty of firm communication, the mere presence of any eco-claim positively affects purchasing intention. Similarly, the study by Atkinson and Kim (2014) indicates that consumers use rationalization in order to balance their skepticism of greenwashed communication and ultimately accept the claims. Parguel et al. (2015) show that executional greenwashing in the form of

nature-evoking elements in advertisements is effective in misleading consumers in their evaluation of a brand's ecological image, especially if they have low knowledge of environmental issues.

On the other hand, Chen and Chang (2013) find that greenwashing increases consumer confusion and perceived risk, reducing consumers' trust towards product's environmental performance. Parguel et al. (2011) investigate the influence of independent sustainability ratings on consumers' attitude towards CSR communication. The results show that in the case of CSR communication a poor sustainability rating has a negative influence on corporate brand evaluations, since consumers perceive sustainability activities of the brand as not intrinsically motivated. Nyilasy et al. (2014) show that low environmental performance has negative effect on brand attitude and that this effect is strengthened by the greenwashing communication. Additionally, Majláth (2017) finds that greenwashing information significantly decreases the ad evaluation. Finally, the recent study by Jong et al. (2017) indicates that even when consumers know that green claim is untrue or misleading, greenwashing organizations create a more favorable image than silent brown organizations. However, the results of the study also show that greenwashing has a detrimental effect on perceived communicative integrity and does not affect consumers' purchase intentions, "so it is a useless, myopic strategy" (Jong et al. 2017, p. 24).

Solutions to Greenwashing

The literature on greenwashing describes three specific mechanisms for deterring this phenomenon: pressure from civil society, ecolabeling, and government regulation and legislation (Lyon and Montgomery 2015). First strong environmental groups may limit greenwashing through public exposure of dishonest corporate behavior. The power of civil society is additionally reinforced by the emergence of social media that not only stimulates free flow of information among stakeholders leaving most the corporations "naked"

(Tapscott and Ticoll 2003), but also enables stakeholders to self-organize and impose real, tangible pressure on organizations (Shirky 2008). Another approach to deterring greenwashing is the use of environmental certification by trusted third parties (ecolabeling), such as Fairtrade, Rainforest Alliance, FSC, or EU Ecolabel. However, the proliferation of organizations issuing ecolabels together with poor monitoring and usage of false ecolabels results in information overload and consumer confusion. Finally, government oversight and regulation are viewed as important mechanisms reducing dishonest environmental communication.

Guidance on Social Responsibility

Biljana Tošić

Faculty of Organizational Sciences, University of Belgrade, Belgrade, Serbia

Synonyms

[The international standard on social responsibility](#); [The ISO standard on social responsibility](#)

Definition

ISO 26000:2010 – “Guidance on Social Responsibility” is one of the most popular standards for social responsibility (ISO [2017b](#)). ISO 26000:2010 was created in 2010 by more than 500 different stakeholders gathered around the ISO Working Group on Social Responsibility (ISO/WG–SR) – and reviewed and confirmed in 2017 – “so this version remains current” (ISO [2020a](#)). ISO 26000:2010 aims at assisting contemporary organizations to contribute to sustainable development by encouraging them to go “beyond the basic legal compliance” (ISO [2018a](#)). This standard aims at offering a more complete and extensive understanding of social responsibility – “while complementing, not replacing – existing tools and activities” (ISO [2018a](#)). Moreover, it aims at offering support, guidance, and recommendations on how

contemporary organizations can execute daily tasks in a socially responsible manner and tends to clarify, simplify, and support different activities aimed at achieving sustained success (ISO 2010). Since it does not contain requirements, ISO 26000:2010 is not a certification standard – “any offer to certify or claims to be certified to ISO 26000 would be considered as misrepresentation of its intent and purpose” (ISO 2018a). To date, ISO 26000:2010 has been successfully implemented in more than 80 economies and is one of the documents “upon which the European Commission built its corporate social responsibility (CSR) strategy” (ISO 2017b).

Introduction

To date, most contemporary organizations have been starting to pay much more attention to social responsibility and socially responsible behavior. Strong organizational efforts and joint “commitment to the welfare of society” are becoming much more significant for all of the stakeholders and interested parties concerned with the overall organizational performance and an organization’s ability to successfully carry forward (ISO 2018a). This seems to stress out the growing significance of (corporate) social responsibility, social equity, and organizational governance (ISO 2018a). Such social responsibility and socially responsible behavior shall, ultimately, contribute to sustainable development (ISO 2018a). The need to explore some of the concepts further was first recognized in 2001 by the ISO Consumer Policy Committee (ISO/COPOLCO). As a result, in 2003, the ISO Technical Management Board (ISO/TMB) set out “the ISO Ad-Hoc Group on Social Responsibility (ISO/AHG–SR)” to explore these concepts further (ISO 2008). Following the guidelines and recommendations from the ISO conference (2004) – “the ISO Working Group on Social Responsibility (ISO/WG–SR)” was established to develop the standard on social responsibility, today known as ISO 26000:2010 (ISO 2008).

The concept of sustainable development (as developed in ISO 26000:2010) can be defined

as “a form of development that meets the needs of the present without compromising the ability of future generations to meet their own needs” (ISO 2018b). Accordingly, an organization’s contribution to sustainable development (“and its impact on the society and an environment”) – can be defined as social responsibility (ISO 2018b). Social responsibility can be defined as “the responsibility of an organization for the impacts of its decisions and activities on society and the environment, through transparent and ethical behavior that contributes to sustainable development, takes into account the expectations of stakeholders, is in compliance with the applicable law and consistent with the international norms of behavior, and is integrated throughout the organization and practiced in its relationships” (ISO 2018b). Considering that all organizations shall contribute to sustainable development (not just corporate businesses) – the previously established term “the corporate social responsibility” was replaced with the term “the social responsibility” – as it now seems to be much more appropriate (ISO 2010).

Benefits of Adopting ISO 26000

According to ISO (2018a), adopting ISO 26000 can lead to several benefits –

- Ensure a competitive advantage at the market and enhance global competitiveness;
- Enhance the morale, engagement, and the commitment of employees;
- Enhance attracting and retaining employees, customers, and other stakeholders;
- Strengthen the organization’s reputation, brand, and image at the local community;
- Strengthen the relationship with the financial community (e.g., donors and sponsors);
- Strengthen the relationship with the global community (e.g., governments and media);

Principles

As stated by several ISO documents, the strategic goal for most contemporary organizations shall be

seen as “to maximize the organizational contribution to sustainable development” (ISO 2010). Aiming to achieve the aforementioned goal, organizations should address the following principles (Clause 4 of ISO 26000:2010 offers guidance on these seven principles) (ISO 2010) –

- “[Principle 1] Accountability”
- “[Principle 2] Transparency”
- “[Principle 3] Ethical Behaviour”
- “[Principle 4] Respect for Stakeholders Interest”
- “[Principle 5] Respect for the Rule of Law”
- “[Principle 6] Respect for International Norms of Behaviour”
- “[Principle 7] Respect for Human Rights”

Accordingly, ISO (2010) suggested that contemporary organizations should always act by following these principles – even when found in the most difficult situations and contexts.

Structure

The content of seven clauses of ISO 26000:2010 can be summarized as follows (ISO 2010) –

- **Clause 1** defines the scope and “certain limitations and exclusions”;
- **Clause 2** offers the terms and definitions of social responsibility;
- **Clause 3** defines the concept of social responsibility, as well as, all of the key factors that have influenced the development of the concept of social responsibility;
- **Clause 4** offers “guidance on seven principles of social responsibility”;
- **Clause 5** defines two fundamental approaches when addressing social responsibility – it explores the linkages “between an organization, stakeholders, and the society,” and the seven core subjects (as well as issues and expectations) of social responsibility;
- **Clause 6** explores the seven core subjects of social responsibility: for each subject – the scope of the subject, the relationship between subjects and social responsibility, “associated

principles and considerations, and all related actions and expectations”;

- **Clause 7** explains how to “integrate social responsibility throughout the organization” by raising awareness and capacity building of “governance, systems, and procedures”;
- **Annex A** offers “examples of voluntary initiatives and tools for social responsibility”;
- **Annex B** offers abbreviated terms used in ISO 26000:2010;

Figure showing the schematic overview of ISO 26000:2010 can be found at the ISO platform (ISO 2020b).

Core Subjects

There are seven core subjects of social responsibility given in Clause 6 of ISO 26000:2010, with the associated social responsibility issues, actions, and expectations (ISO 2018b) (Table 1)–

Figure showing the seven core subjects of ISO 26000:2010 can be found in ISO 26000:2010 (ISO 2010).

Sustainable Development Goals (SDGs)

Although ISO 26000:2010 was developed “before the United Nations (UN) 2030 Agenda” and UN Sustainable Development Goals (SDGs) – it offers more than 450 guidelines and “recommendations related to its main principles and core subjects of social responsibility that help organizations contribute to the SDGs” (ISO 2018b). Not only does ISO 26000:2010 assist organizations from around the world to act in a socially responsible manner – but it also assists them to develop specific tools and actions that should be undertaken for this purpose (ISO 2018b). According to ISO (2018b), these actions usually line up with other regulations and international norms of behavior, as “the Universal Declaration of Human Rights” and “the International Labour Organization Core Conventions on Labour Practices” (ISO 2018b).

Guidance on Social Responsibility, Table 1 The seven core subjects of social responsibility. (Source: adapted from ISO 2018b)

Core Subjects/ Issues	Title	Clause
Core Subject 1	“Organizational Governance”	6.2.
Core Subject 2	“Human Rights”	6.3.
Issue 1	“Due Diligence”	6.3.3.
Issue 2	“Human Right Risk Situation”	6.3.4.
Issue 3	“Avoidance of Complicity”	6.3.5.
Issue 4	“Resolving Grievances”	6.3.6.
Issue 5	“Discrimination and Vulnerable Groups”	6.3.7.
Issue 6	“Civil and Political Rights”	6.3.8.
Issue 7	“Economic, Social, and Cultural Rights”	6.3.9.
Issue 8	“Fundamental Principles and Rights at Work”	6.3.10.
Core Subject 3	“Labour Practices”	6.4.
Issue 1	“Employment and Employment Relationships”	6.4.3.
Issue 2	“Conditions of Work and Social Protection”	6.4.4.
Issue 3	“Social Dialogue”	6.4.5.
Issue 4	“Health and Safety at Work”	6.4.6.
Issue 5	“Human Development and Training in the Workplace”	6.4.7.
Core Subject 4	“The Environment”	6.5.
Issue 1	“Prevention of Pollution”	6.5.3.
Issue 2	“Sustainable Resource Use”	6.5.4.
Issue 3	“Climate Change Mitigation and Adaptation”	6.5.5.
Issue 4	“Protection of Environment, Biodiversity, and Restoration of Natural Habitats”	6.5.6.
Core Subject 5	“Fair Operating Practices”	6.6.
Issue 1	“Anti-Corruption”	6.6.3.
Issue 2	“Responsible Political Involvement”	6.6.4.
Issue 3	“Fair Competition”	6.6.5.
Issue 4	“Promoting Social Responsibility in the Value Chain”	6.6.6.
Issue 5	“Respect for Property Rights”	6.6.7.
Core Subject 6	“Consumer Issues”	6.7.
Issue 1	“Fair Marketing, Factual, and Unbiased Information and Fair Contractual Practices”	6.7.3.
Issue 2	“Protecting Consumers’ Health and Safety”	6.7.4.
Issue 3	“Sustainable Consumption”	6.7.5.
Issue 4	“Consumer Service, Support, and Complaint and Dispute Resolution”	6.7.6.
Issue 5	“Consumer Data Protection and Privacy”	6.7.7.
Issue 6	“Access to Essential Services”	6.7.8.
Issue 7	“Education and Awareness”	6.7.9.
Core Subject 7	“Community Involvement and Development”	6.8.
Issue 1	“Community Involvement”	6.8.1.
Issue 2	“Education and Culture”	6.8.2.
Issue 3	“Employment Creation and Skills Development”	6.8.3.
Issue 4	“Technology Development and Access”	6.8.4.
Issue 5	“Wealth and Income Creation”	6.8.5.
Issue 6	“Health”	6.8.6.
Issue 7	“Social Investment”	6.8.7.

According to ISO (2018b), ISO 26000:2010 assists contemporary organizations to –

- Evaluate how organizations impact society and contribute to sustainable development;
- Determine and manage expectations of stakeholders and interested parties;
- Determine the most relevant issues and prioritize actions according to them;
- Comply with international documents, and conform with other rules and regulations;
- Implement and coordinate social responsibility principles throughout the organization;

The ISO 26000 Post Publication Organization (PPO) was established by ISO/TMB in 2010 (and was disbanded July 18, 2018) as “a non-formal body (e.g., committee, working group)” (ISO 26000 INFO 2020c). The ISO 26000 PPO aimed at developing documents that support the understanding of ISO 26000 (ISO 26000 PPO 2017). Following the conclusions derived from stakeholders meeting that was held in 2016, in Stockholm (Sweden), ISO 26000 PPO aimed at assisting ISO to develop a special guide on ISO 26000:2010 and SDGs (ISO 26000 PPO 2017). Although this guide “did not consider UN SDG 17 nor the alphabetical goals as these are oriented towards states and not towards organizations” (ISO 26000 PPO 2017) – the guide offered guidelines on how organizations can contribute to the UN 2030 Agenda and the UN SDGs by using ISO 26000:2010 “as a complementary tool” (United Nations 2019).

This guide offered two different approaches (ISO 26000 PPO 2017) –

- Table A: From Issue to Target – can be used to identify which of the ISO 26000:2010 actions contributes to which UN SDGs and targets.
- Table B: From Target to Issue – can be used to identify which UN SDGs and targets are not yet covered by the ISO 26000:2010 actions and recommendations.

As mentioned by ISO 26000 INFO (2020c), disbanning the ISO 26000 PPO (2010–2018) after

8 years of developing the ISO 26000 global community had several consequences –

- All real and potential, current and future (global and regional) questions regarding the adoption of ISO 26000:2010 will be carried through the ISO Central Secretariat and ISO/TMB, local questions will be carried through National Standards Bodies (NSBs).
- The review of ISO 26000:2010 (every 3–5 years) will be conducted by the ISO/TMB.
- All documents developed by the ISO 26000 PPO will not be adapted and/or updated – at least – “unless and until a new version of ISO 26000 is formed and recognized”.

There is a belief that a complete and comprehensive understanding of social responsibility and socially responsible behavior (as concepts used in ISO 26000:2010) shall contribute to the achievement of SDGs (ISO 2020d). The global recognition of ISO 26000:2010 shall be seen as crucial for “ensuring that the SDGs are met and our planet’s sustainability secured” (ISO, 2020d).

Summary

ISO 26000:2010 refers to the most popular international standard on social responsibility that is meant to be implemented by contemporary organizations that tend to execute daily tasks in a socially responsible manner. ISO 26000:2010 was created as a result of the growing needs of more than 500 stakeholders to address social responsibility and sustainable development. ISO 26000:2010 aims at assisting contemporary organizations to contribute to sustainable development by offering a more complete and comprehensive understanding of (corporate) social responsibility and socially responsible behavior. ISO 26000:2010 is not a management system standard – it contains guidelines, not requirements – so it is not meant to be certified to. Following the guidelines and recommendations given in ISO 26000:2010 – contemporary organizations shall add value, enhance employees’ morale, engagement, commitment,

strengthen the local and the global community, and contribute to the achievement of the SDGs.

Hampel Report (UK)

Louise Gorman¹ and Anne Marie Ward²

¹Technological University Dublin, Dublin, Ireland

²Ulster Business School, Ulster University, Newtownabbey, Northern Ireland

Description

The *Hampel Report* is the shortened name for the *Final Report of the Committee on Corporate Governance* published by the Committee on Corporate Governance (1998) (hereafter called the “Hampel Committee”) under the chairmanship of Sir Ronald Hampel. The *Hampel Report* presents an assessment of the extent to which the objectives of best practice recommendations on corporate governance, as detailed in the *Cadbury Report* (1992) and the *Greenbury Report* (1995), were being achieved by corporates listed on the London Stock Exchange (notably FTSE 100 corporations). In addition to this, it also provides further recommendations to public-listed corporations on methods of providing enhanced protection to their shareholders and advises shareholders on how to strengthen their voice in investee corporations. The report establishes a set of principles of best practice in corporate governance, many of which persist in the present-day *UK Corporate Governance Code* (FRC 2018). This entry begins by setting the background to the

report. Next the findings of the committee, its recommendations, and the principles of the report are reviewed. Finally, the significance and effectiveness of the *Hampel Report* is evaluated.

Background

Established in 1995, upon the initiative of the Financial Reporting Council, the Hampel Committee’s objectives were, firstly, to review the implementation of the Cadbury recommendations; secondly, to address issues emerging from the *Greenbury Report*; and thirdly, to “look afresh” at the roles of directors, shareholders, and auditors in corporate governance (para. 1.6). The committee consulted with corporations and individuals including public corporations and institutional investors. The output from the committee’s investigations, the *Hampel Report*, notes enhancements in transparency and accountability with respect to trading results, audited financial statements, operations, and remuneration stemming from the work of the Cadbury and Greenbury committees. However, it advises that corporate governance extends beyond accountability. The Hampel Committee concurred with its predecessors to the extent that rigid governance rules are inconsistent with the diversity of circumstances and experiences among corporates and sought to avoid encouraging a box-ticking approach to governance. The *Hampel Report* distinguishes governance principles from guidelines,

noting that the former tends more to provoke inquiry into the manner of application rather than simply whether, or not, they are being applied. In this vein, the *Hampel Report* submits principles of corporate governance and recommends that corporates include in their annual reports a narrative statement of how they apply the relevant principles, to their particular circumstances (para. 2.1).

The principles in relation to directors, shareholders, and auditors are now summarized.

Directors

Section A of the principles, which deals with directors, reinforces the importance of separating the roles of chief executive officer and chairman to effective board leadership (principle A2). The *Hampel Report* advocates the appointment of a senior independent board member as a potential sounding board in circumstances where concerns cannot be conveyed to the chairman and suggests details of the senior independent director be disclosed in the annual report (para 3.18). The *Hampel Report* extends the work of Cadbury by emphasizing the role of nonexecutive and independent directors in avoiding executive dominance (principle A3). To reduce the ability of a dominant director to control appointments, the report recommends a formal procedure for board appointments implemented primarily through a nominations committee (principle A5). A further consideration is duration of service. In respect of this, the recommendations of institutional investors, including the UK National Association of Pension Funds and the Association of British Insurers, that directors be re-elected every 3 years are acknowledged (para 3.21) and reflected in the principles (principle A6). With regard to service contracts, the *Hampel Report* supports a reduction of directors' contracts to 1 year where feasible (para 4.9). Such a reduction would further limit the potential for directors to become entrenched within the corporate, by virtue of their tenure.

The report notes the dependence of board effectiveness on the form, timing, and quality of the information it receives from management. While the *Hampel Report* does not signify who should have responsibility to ensure an adequate supply of information to the board, reference is made to the *Cadbury Report's* view that it is the chairman's responsibility to ensure the board is briefed on all issues arising at board meetings (para 3.4). The *Hampel Report* also supports Cadbury on the area of induction and training of new directors, commenting that further periodic training is equally as important as initial training (para 3.5).

Section B of the principles addresses remuneration. The Hampel Committee could not fully assess the extent to which the objectives of the Greenbury committee were being achieved as only one full reporting cycle had occurred between the implementation of the Greenbury recommendations on 31 December 1995 and the finalization of the *Hampel Report*. However, the *Hampel Report* explicitly sets out the principle that no one executive director should be involved in the determination of his own pay (principle B2). There is some deviation from the Greenbury recommendations, which places the responsibility for disclosure of remuneration arrangements with the remuneration committee, as the *Hampel Report* places responsibility for disclosure of remuneration with the whole board (principle B3).

The recommendation by Greenbury that remuneration be disclosed in annual reports caused controversy. Despite this, the *Hampel Report* strongly advocates continuance of transparent reporting, though acknowledges that it may result in upward pressure on pay, given the competitive market for managerial talent (para 4.5). In addition, the level of detail in remuneration disclosures is acknowledged as often excessive; however, this is attributed to the legal and regulatory infrastructure in place, whereby disclosures are required to satisfy multiple requirements of various constituencies. In response to the view that the recommended disclosures are excessive, the *Hampel Report* welcomes streamlining the

legal and regulatory requirements and encourages authorities to explore the scope for simplification (para 4.16). The Greenbury recommendations on linking pay to performance as a means of promoting the maximization of shareholder wealth are supported (para 4.6). The *Hampel Report* advances this by urging remuneration committees to use informed judgment in devising remuneration schemes that are specific to the corporate's circumstances. It is advised that the design of such schemes ought to be understandable from a shareholder's perspective (para. 4.7). To further promote understandability, the *Hampel Report* advocates clear and accurate disclosure of directors' pensions, noting they represent a long-term cost to the corporate (para 4.19) and supports the *Greenbury Report* in the recommendation that shareholders be invited to approve all long-term incentive plans (para 4.20). Consistent with the *Greenbury Report*, the *Hampel Report* holds short of recommending a need for shareholder approval of the remuneration report, reasoning that shareholders may choose to vote against all of the annual report and financial statements, if their concern is sufficiently strong (para 4.21).

Finally, in recognition of the difficulties encountered in the compensation of departing directors, the *Hampel Report* recommends that corporates make detailed provision at the outset as to the payments a director would be entitled to, in the event of early termination of contract (para 4.10).

Shareholders

The *Hampel Report* is clear in its view of the fiduciary duty of corporate directors. In paragraph 1.6 it states that "The single overriding objective shared by all listed companies, whatever their size or type of business is the preservation and the greatest practical enhancement over time of their shareholders' investment." This provides overwhelming support for the primacy of shareholders over other stakeholders. To this end, section C of the *Hampel Report* includes principles relating to

both the role of shareholders and the relationships that listed corporations maintain with their shareholders. In particular, the *Hampel Report* emphasizes the importance of engagement and dialogue between the corporation and its shareholders.

The Hampel Committee's work came at a time when institutional ownership of UK-listed shares was high; the *Hampel Report* claims that 60% of UK-listed corporate shares were in the hands of institutions such as pension and insurance funds (para 5.1). These institutions employ market experts and are specialist in investing funds. Yet despite the high percentage of institutional ownership, research undertaken by the Hampel Committee found a lack of meaningful engagement and voting at investee corporations by institutional investors (para 5.2; 5.7; 5.10), with some exceptions (para 5.3). In response to this finding, the *Hampel Report* urges institutional shareholders to take responsibility for their investments and to make considered use of their votes (principle C1). Moreover, the report advocates dialogue between institutional investors and listed corporations (principle C2). However, the *Hampel Report* acknowledges that the number of opportunities for such engagement is limited in practice. The *Hampel Report* recommends that major institutions review voting guidelines to ensure consistency with each other and with best practice recommendations in governance (para 5.8).

Consideration is also given to smaller private investors by pointing toward the AGM as an opportunity for their contribution to the governance of the corporations in which they invest (principle C4). The *Hampel Report* welcomes initiatives to facilitate an improved flow of information to private shareholders by the UK Department of Trade and Industry and HM Treasury (para 5.25).

Financial Statements, Internal Control, and Auditors

The principles set out in section D are relevant to both listed corporations and auditors. The Hampel

Committee expands the focus given by the Cadbury Committee on the capacity of the annual financial statements to provide a balanced and understandable assessment of the corporate's position and prospects. The Hampel principles encompass the extent to which the annual report and other relevant reports to shareholders and other stakeholders provide such a view (principle D1). It also notes that internal control extends beyond financial controls to include operational, compliance, and risk management which may also impact shareholders' interests (principle D2). The principles echo the views of the Cadbury Committee regarding the audit committee's composition and responsibilities (principle D3). Specifically, it reinforces the recommendations made in the *Cadbury Report* that the audit committee consist of a majority of independent members; take primary responsibility for reviewing the strength of internal control; and take primary responsibility for the quality and accuracy of financial information disclosed to shareholders (para 4.35). With regard to the external auditor, the *Hampel Report* is careful to acknowledge the dual role of the auditor to report to shareholders in accordance with its legal and regulatory requirements, while reporting to the board privately on operational and other matters (principle D4). The potential for audit firms' reliance on single corporations for income from both audit and non-audit services to impair independence is noted, and bodies within the profession (para 6.8) and audit committees (para 6.9) are encouraged to review this risk.

Summary

The *Hampel Report* is primarily recognized for reinforcing the importance of corporate governance as a method of shareholder protection and for its emphasis on the positive contribution of governance to corporations (Short et al. 1999). It emphasizes the importance of taking a "principles" approach to corporate governance rather than creating recommendations that can be

achieved by undertaking a "tick-box" exercise. This shift in emphasis makes the *Hampel Report* one of the most important documents in the evolution of corporate governance codes in the UK. Nevertheless, it is argued that the *Hampel Report* did not go far enough. For example, Dignam (1998) argued that some of the *Hampel Report's* short-term-oriented references, such as those relating to 1-year limits on directors' contracts (para. 4.9), are inconsistent with the pursuit of long-term governance issues. Indeed, this is now generally regarded as a key element to sustainable corporate success (UK Stewardship Code 2012, principle 1).

Furthermore, Webb et al. (2003) consider that the report does not provide sufficient recommendations to counter free-rider problems which have long been acknowledged as a barrier to effective shareholder activism. Finally, the *Hampel Report's* clear support for the primacy of shareholders is no longer supported by policymakers. It has been replaced by a view that directors have a fiduciary duty toward a wide range of stakeholders that includes shareholders (Sullivan et al. 2015). Its criticisms notwithstanding, the *Hampel Report* did highlight the importance of shareholder engagement and dialogue and paved the way for the Financial Reporting Council's publication of the *Combined Code on Corporate Governance* (1998). This *Code* and its subsequent editions provided the framework for the governance of UK and Irish-listed companies for the following 12 years. Many of the core principles of the *Hampel Report* endure in the current *UK Corporate Governance Code*. Indeed, the current *UK Corporate Governance Code* is reflective of the *Hampel Report* in various respects, including but not limited to its unambiguous recommendations that the roles of the board's leaders be separated (provision 9); that the board performs an important role in managing operational and compliance as well as financial risk (provision 29); and that directors' involvement in the determination of their own remuneration should be avoided (principle Q).

Happy Planet Index

Alexandra Korcheva
Sofia university “St. Kliment Ohridski”,
Sofia, Bulgaria

Synonyms

[HPI](#)

Definition/Description

The Happy Planet Index (HPI) is a complex index that aims to measure sustainable well-being and happiness of nations (HPI 2020). It compares how efficiently residents of different countries are using natural resources to achieve long lives and high well-being.

The Happy Planet Index comprises of four main indicators – life expectancy, experienced well-being, inequality of outcomes, and ecological footprint (HPI 2016). It measures the relation between these four components in calculating the overall levels of sustainable well-being of nations.

The index shows data in an interactive way, with possibilities to both view rankings of countries by each criterion separately, and as an overall result. The index often shows that despite having higher index ranking on overall income and life expectancy, wealthy Western countries “often seen as the standard of success” do not rank as highly on the overall Happy Planet Index. Instead, the index shows that several countries in Latin America and the Asia Pacific region lead the way by achieving high life expectancy and well-being with much smaller ecological footprints.

The HPI calculates the sustainable well-being of more than 140 countries (HPI 2016).

Unlike other indices that measure happiness, the HPI puts a stress on the balance between individual well-being and ecological status of the surrounding environment (HPI 2020). It aims to emphasize on acknowledging that individual

well-being strongly depends on the state of the environment one lives in as well as the overall incomes and life expectancy (HPI 2020). The index provides a measurement of the levels of happiness in a nation a bit different than some of the more popular happiness indices, and a different – more oriented toward environmental balance – point of view on the “happiness on a collective level” understanding.

Description of the Index

The Happy Planet Index measures the levels of happiness in more than 140 countries. It focuses on four different criteria to derive the overall HPI index measure (HPI 2020).

The Happy Planet Index (HPI) is a complex index that comprises four elements – ecological footprint, well-being, life expectancy, and inequality (HPI 2016).

- **Life expectancy** – the average number of years an infant born in that country is expected to live if prevailing patterns of age-specific mortality rates at the time of birth in the country stay the same throughout the infant’s life. Data is taken life expectancy data for the year 2012, prepared by the Population Division of the Department of Economic and Social Affairs of the United Nations. The Happy Planet Index uses an inequality-adjusted life expectancy index which is calculated using the UNPD data, adjusted through an Atkinson index that takes into account not only the mean life expectancy but the geometric mean life expectancy as well (HPI 2016).
- **Experienced well-being** – the experienced well-being element of the Happy Planet Index is calculated using the Gallup World Poll data. The Gallup World Poll measures the life satisfaction of people in different countries by establishing the average of all responses from within the population of a country. The Happy Planet Index uses an inequality-adjusted experienced well-being element, which is derived through an Atkinson indices for experienced well-being (HPI 2016).
- **Inequality of outcomes** – a measure of how unequal the distribution of life expectancy and experienced well-being scores are within a particular country. The inequality of outcomes measure is the difference in the product of mean life satisfaction and mean experienced well-being, and the product of inequality-adjusted life satisfaction and inequality-adjusted experienced well-being, expressed as a percentage. The index uses an inequality-adjusted experienced well-being (HPI 2016).
- **Ecological footprint** – the average amount of land needed, per head of population, to sustain a typical country’s consumption patterns. It includes the land required to provide the renewable resources people use (most importantly food and wood products), the area occupied by infrastructure, and the area required to absorb CO₂ emissions. Crucially it is a measure of consumption, not production. This means that, for example, the CO₂ associated with the manufacture of a mobile phone made in China but bought by someone living in Chile will count toward Chile’s ecological footprint, not China’s. ecological footprint and is expressed using global hectares as a standardized unit (HPI 2016).

The Happy Planet Index is calculated for a given country by combining the main components in the following equation (HPI 2016):

$$\text{Happy Planet Index} \approx \left(\frac{\text{Life expectancy}}{\text{x Experienced wellbeing}} \right) \times \text{Inequality of outcomes/Ecological Footprint}$$

The index provides a website visualization of the data with color-coded world maps that show the levels of happiness in all countries measured. The color coding follows the traffic light paradigm.

Measuring Happiness

In 2011, the UN General Assembly adopted resolution 65/309 titled *Happiness: Towards a Holistic Definition of Development* with which it

invited member states to measure the levels of happiness of their peoples and use the data for a guide for public policy decision-making (UN 2011). In 2012 the resolution was followed by the first UN High-Level Meeting on *Wellbeing and Happiness: Defining a New Economic Paradigm* (Royal Government of Bhutan 2012). A whole new movement in measuring national well-being emerged that focused not so much on standard criteria as GDP for measuring well-being but instead trying to focus on more intangible factors associated with the feeling of happiness and life satisfaction of people.

More well-known periodical measurements of national happiness are the World Happiness Report of the UN and the Happiness Index. The Gross National Happiness concept has been of growing interest among scholars and policy makers, with the nation state of Bhutan even having implemented an official Gross National Happiness Index of the country (Metz 2014).

The debate around measuring happiness has been a hot topic in economics (Weimann et al. 2014), sociology, psychology, and political science. It has always been a topic of dispute on whether happiness could be measured at all, as it is too much a subjective category (Bates 2009). Happiness has mostly been object of thought on the individual, rather than collective level. However, recent advances in social science have, however, led to the reconsideration of the standard statistical measurements of success and welfare in different countries. Until recently, GDP per capita has been considered the main and most important number for measuring the success of the members in a society. However, it is recognized that this index brings little or no actual knowledge of the happiness of people in a country (UN 2011).

Including different additional factors (as inequality levels, institutional performance, and good governance), a more precise picture of the actual state of people's satisfaction is being introduced in recent years.

However, it is still a difficult task to establish a firm connection between factors such as consumption, social inclusion, good governance, etc., and the elusive category of happiness.

Summary

The Happy Planet Index is an instrument for measuring the overall well-being and life satisfaction of nations emphasizing on the feeling of satisfaction, longevity, and ecological footprint. It is a tool that can help enrich the perspective of levels of happiness within a nation. However, measuring happiness is still an elusive task for statistical analysis, as the feeling of happiness is still a highly subjective and individual-specific psychological category.

Definition

Health and safety in the workplace, also known as occupational health and safety and occupational hygiene, is a multidisciplinary field that involves medicine, law, management, and organizational studies. It relates to the employer's duty to provide a safe workplace as a necessary condition to preserve workers' health and well-being.

To fulfill such legal and social responsibilities, employers have to identify health and safety hazards, i.e., anything that has the potential to harm workers or provoke illnesses. Hazards may consist in work materials, equipment, work methods

and practices, workplace layout, and microclimate. Moreover, hazards may derive from workloads and other organizational aspects. The combination of the likelihood that somebody may suffer an occupational injury or disease and the estimated consequences for that person and for others (such as colleagues and visitors) determine the so-called occupational risk, which employers are supposed to minimize through the implementation of occupational health and safety risk management.

The provision of healthy and safe working conditions is also required by the 2030 Agenda for Sustainable Development, which specifically aims to ensure a decent work to all people (SDG 8) and to support good health and well-being (SDG 3).

Introduction

In today's macroeconomic system and business environment, sustainability is the key to long-term success. Organizations that intend to properly balance their financial results with ecological concerns and the well-being of people cannot disregard occupational health and safety. Ensuring safe and healthy conditions for all workers and contractors is broadly perceived as a fundamental part of corporate responsibility. However, the frequency of work-related injuries and diseases is still too high and provokes serious consequences for the individuals who are directly affected, their families, and society at large.

On a strictly economic basis, the International Labour Organization (ILO) estimates that more than 4% of the world's GDP is lost every year because of accidents at work and occupational illnesses (ILO 2022). Besides, work-related health problems give rise to major expenditures for governments and enterprises.

Social disparity also derives from occupational health and safety. Death and disability resulting from hazardous work is the main cause of poverty for many families. Moreover, as poor countries are those with the highest concentration of work-related injuries and diseases, the lack of effective measures to face this problem may even widen the gap between developing nations and advanced ones.

According to the ILO, a vicious circle emerges from insufficient health and safety in the workplace and involves workers' economic and social spheres. In fact, poor health reduces people's working capacity, with repercussions for their productivity and salaries, on the one hand, and life expectancy, on the other. Obviously, all of this also affects the quantity and quality of human resources that companies may employ, as well as the amount of financial resources available for investment in health and safety measures, which could even decrease.

Governments, which are expected to combat social inequalities and poverty, should therefore adopt remedies for irregular and low-quality employment and lack of social protection. Their commitment should also be accompanied by the efforts of labor and business organizations to improve workplace health and safety culture, which must be a priority in the pursuit of sustainable development worldwide.

Not surprisingly, occupational health and safety is one of the fields covered by the 2030 Agenda for Sustainable Development, adopted by all United Nations Member States in 2015 in order to achieve 17 Global Goals (also known as the Sustainable Development Goals or SDGs) concerning peace and prosperity for people and the planet. Health and safety in the workplace is mainly related to two of the Global Goals, namely, SDG 3 and SDG 8, to be achieved by 2030.

SDG 3 concerns "Good health and well-being" and it is classified as a "health goal." Among others, SDG 3 includes Target 3.9, which aims at a substantial reduction in the number of deaths and illnesses from hazardous chemicals and air, water, and soil pollution and contamination. Evidently, this requires rethinking the industrial processes that still use dangerous substances and replacing these latter, in order to minimize the number of workers exposed to harmful consequences, whether immediately or in the long term.

SDG 8 regards "Decent work and economic growth"; therefore, it is considered a "jobs goal." SDG 8 comprises Target 8.8, which calls for the protection of labor rights and the promotion of safe and secure working environments for all workers, including migrant workers, in particular

women migrants, and those in precarious employment. An organization that effectively addresses this matter can turn the vicious circle described above into a virtuous one, which generates advantages not only for the workers, but also for the organization itself and society.

Indeed, an organization that provides healthy and safe working conditions creates a positive climate for workers, which increases their attachment to work and their productivity in performing tasks; in addition, it plays a pivotal role in trust building, thus making internal relationships easier. External relations also benefit greatly from a healthier and safer workplace, because this helps strengthen the company's image and market position and obtain approval from stakeholders, which is an essential requirement for sustainable success.

Occupational Health and Safety as a Global Issue

Health and safety in the workplace is a fundamental right of any worker and it should be a primary goal of all organizations (Koradecka 2010; Burke et al. 2016; Reese 2016). Ensuring well-being of workers and preventing work-related injuries and diseases are also the main objectives of strategic programs that complement mandatory law provisions in a number of countries.

For example, the "EU Strategic Framework on Health and Safety at Work 2014–2020" aims to improve the implementation of existing rules on health and safety in the European Union, especially through the promotion of effective occupational risk management in small enterprises. Moreover, the Strategic Framework intends to raise awareness on new and emerging risks, also taking into account the ageing of the EU's workforce.

At supranational level, the commitment of the International Labour Organization (ILO), the World Health Organization (WHO), and the Organisation for Economic Co-operation and Development (OECD) is crucial for achieving a sound cooperation between governments, trade unions, and employer organizations, so that occupational health and safety can actually be implemented in

businesses. Indeed, health and safety at work is still an open question, despite the broad debate on work-related issues that constantly occupies political, economic, and social agendas of institutions all over the world.

All business organizations are therefore supposed to take an active role, establishing processes aimed at managing occupational risks. To be effective, occupational health and safety risk management should eliminate or at least reduce incidents, which OHSAS 18001:2007 defined as “work-related event(s) in which an injury or ill health (regardless of severity) or fatality occurred, or could have occurred.”

Incidents can be classified into two categories: accidents, if an injury or illness actually occurs, and near-misses, if no injury or illness occurs (Marek and Bugajska 2010). Investigating and understanding the causes of near-misses is fundamental to avoiding future accidents.

Occupational injuries are wounds or damages to the body, which can be originated by physical, chemical, biological, or psychosocial factors. For example, occupational injuries include burns due to chemical substances or fire, but also muscle pain caused by lifting, pulling, pushing, and carrying materials or equipment, as well as bruises, lacerations, and broken limbs from slipping or tripping, falling from heights (roofs, ladders, stairways, and scaffolding), running into a glass door, and being hit by falling objects and broken glass.

Work-related diseases result from exposure to one or more risk factors arising from work activities. Occupational illnesses can be classified into skin diseases or disorders (contact dermatitis, rash, ulcers, etc.), respiratory illnesses (silicosis, pneumonitis, rhinitis, asthma, etc.), poisoning (by mercury, arsenic, carbon monoxide, etc.), hearing and vision loss, work-related cancer, stress, and mental health disorders.

Occupational injuries and illnesses can be fatal, when they lead to the death of the victim within one year of the accident, or not-fatal, when the victim survives (Eurostat 2013). Nonfatal accidents can have temporary or permanent effects on the worker’s health, including living with a disability. Firm-level and macroeconomic consequences can also derive from nonfatal

accidents, such as absence from work; in the most serious cases, workers may be forced to change job or even leave the labor market.

Unfortunately, our economic systems are still in great need of better health and safety at the workplace, as the following data on occupational accidents and diseases clearly confirm.

- a) According to the ILO, occupational accidents and work-related diseases cause 2,300,000 deaths worldwide every year. In addition, 313,000,000 nonfatal injuries result in extended absence from work. The estimated economic impact of poor occupational health and safety practices corresponds to more than 4% of Gross Domestic Product each year (ILO 2022).
- b) In 2019, the EU-28 witnessed 3,140,950 non-fatal accidents (determining at least four calendar days of absence from work) and 3,408 fatal accidents, corresponding to an incidence rate of 1,603 nonfatal accidents and 1.74 fatal ones per 100,000 persons employed. Moreover, work-related accidents more frequently involved men (68% of nonfatal accidents) than women (32%), due to two main factors: the large employment of men in highly hazardous sectors like mining, manufacturing, and construction, and the frequent resort to part-time contracts by women, who spend fewer hours at the workplace than men do (Eurostat 2022).
- c) In 2019, the US private sector reported about 2,800,000 nonfatal injuries and occupational illnesses, with a total incidence rate of 2,800 per 100,000 full-time equivalent workers. Moreover, 5,333 workers died from an occupational injury, accounting for 3.5 per 100,000 full-time equivalent workers. About 20% (1,061) of worker fatalities in private industry were in construction (Bureau of Labor Statistics, United States Department of Labor 2022).

However, the situation is even more alarming, because the official statistics underestimate the phenomenon of occupational injuries and diseases. This is due to the fact that, in some countries, accidents are not systematically reported to the competent agencies. Sometimes, this lack of

reporting depends on the will to hide accidents. Moreover, workers and employers omit to inform the authorities about work-related injuries and illnesses where the legislation does not provide financial incentives to do so: this even happens in some European countries, such as Sweden and the Netherlands (Brück and Lissner 2017).

The context described above requires great attention and specific interventions, as occupational well-being and the prevention of accidents have not only social implications. In a macro-economic perspective, governments are responsible for promoting healthier and safer workplaces, because this increases productivity (thanks to less absenteeism and turnover), diminishes healthcare costs, keeps older workers in employment, and encourages the research for harmless work methods and technologies.

Benefits are also evident for enterprises, in terms of fewer lost working days, fewer threats of legal action to deal with, and better relations with trade unions and public agencies. Workers who appreciate the employer's commitment to health and safety and are involved in training programs are more motivated, with positive effects on their productivity. Generally speaking, companies that care for their personnel's health and safety are perceived as socially responsible, and this boosts their reputation and their relationships with banks, suppliers, customers, and the society at large. In some countries, companies are also financially rewarded if they implement healthy and safe workplaces: for instance, German companies that demonstrate an above-average performance in terms of occupational health and safety benefit from lower insurance premiums, tax reduction, and public grants.

Responsibilities for Health and Safety in the Workplace

The prevention of occupational injuries and illnesses is strictly connected to the formal adoption of a proactive policy and the implementation of a management system, which can also receive an independent third-party certification (e.g., ISO 45001).

In particular, companies of any size and sector should carry out regular assessments of their occupational risks, based on the positive cooperation between employer and workers (or trade unions, acting as employees' representatives). In addition, many other actors from inside and outside the company are involved to ensure effectiveness of occupational risk management.

First of all, public agencies like the European Agency for Safety and Health at Work (EU-OSHA) and the US Occupational Safety and Health Administration (OSHA) contribute to raising awareness of occupational issues. Their activity includes publishing guidelines and standards to help companies implement an appropriate health and safety management system. These agencies also provide training and assistance to firms and develop online interactive tools (e.g., the OiRA project launched by the EU-OSHA) that organizations can directly use in their risk assessment processes. Furthermore, they disseminate information, statistics, and technical reports in order to support the activities of tripartite networks comprising government bodies, employer associations, and trade unions.

At firm-level, employers are responsible for providing a workplace free from serious hazards (Alli 2008). In this regard, they must examine the equipment, substances, and working methods to establish whether they are dangerous for workers. This is an important phase in the risk assessment process, which can obtain better outcomes if it is performed in cooperation with the employees. For this reason, the employer must constantly consult and involve the workers (or their representatives), who have direct knowledge of existing and potential risks to their own health and safety. The cooperation is also critical to the selection of measures to eliminate or reduce hazards.

Other responsibilities of the employer include:

- Keeping the personnel informed about the occupational risks identified and the measures implemented to deal with them
- Providing instructions, assistance, and training, particularly to new and young workers who may have difficulties in perceiving and understanding risks

- Providing collective measures and personal equipment to safeguard workers' health and safety
- Monitoring the effectiveness of collective measures and the proper usage of personal equipment
- Organizing first aid and emergency procedures
- Providing medical examination and taking into account the personal conditions of vulnerable workers, such as pregnant women and people with disabilities
- Conducting investigations after an accident has occurred, recording the results and using them to improve the workplace conditions
- Reporting occupational injuries and illnesses to the national agency and ensuring access to the company's medical records

In large companies, the employer's responsibilities are normally attributed to the CEO, who fulfills them with the support of other managers and under the supervision of the board of directors or a devoted committee. For example, the legislation of several Canada's provinces and the best practices of corporate governance implemented in the country require the establishment of a health and safety committee within the board. The committee is entrusted with developing and implementing appropriate policies and reviewing the company's performance with respect to industrial health and safety matters.

Workers are the other essential actors in occupational risk management. Workers have the right to be informed and consulted with reference to occupational hazards and preventive and protective measures, submit proposals, and receive adequate instructions and training. At the same time, workers must alert their supervisors about perceived risks, use personal protective equipment, and take care of their own health and safety and of that of any other person who may be affected by their conduct.

Especially in complex enterprises, the effectiveness of occupational risk management also depends on the involvement of professionals and consultants, including occupational physicians

with different expertise, such as ergonomists, microbiologists, noise and vibration specialists, occupational hygienists, and psychologists. Doctors provide advice and medical support in the workplace. In particular, they contribute to health surveillance by performing routine check-ups, looking for early signs of work-related stress and illnesses, administering questionnaires to the employees, and keeping records (HSE 2013).

Finally, independent auditors can be hired to provide objective and unbiased opinions on the entire health and safety risk management system.

Occupational Risk Management

Occupational risk management aims to protect workers' health and safety. Regular processes of occupational risk management help employers eliminate hazards from the workplace or at least reduce the likelihood for workers to be harmed while performing their activities (Taylor et al. 2004).

To be effective, occupational risk management requires collecting complete and appropriate information on the hazards in the workplace. Employers are responsible for identifying and removing materials and equipment, as well as rethinking work methods that could potentially provoke nonfatal or fatal injuries to workers, or cause illnesses with immediate symptoms or with occurrence in the long term.

Two aspects must be considered to properly analyze hazards:

- a) The likelihood that they actually harm workers.
- b) The expected severity of impact, i.e., how serious the consequences can be for the workers and, therefore, for the company. Sometimes the assessment must also focus on possible effects for the public, such as visitors and neighbors: for example, a broader consideration of the impact is necessary when the analysis regards industrial processes involving the use of highly flammable materials.

The combination of the likelihood that a hazard can actually harm somebody and its expected impact is defined risk. Health and safety risk assessment is a complex activity, which helps the employer prioritize occupational risks and decide which ones to tackle first. Dealing with such risks means eliminating hazards through the replacement of dangerous substances with harmless ones and the adoption of a different design of work procedures in order to prevent workers from being injured. When definitive solutions cannot be arranged, the employer must look for other types of risk response based on reasonable measures to reduce the likelihood and/or the expected impact of occupational risks.

In order to plan adequate risk responses, the employer should take into account the latest advancements in science, medicine, and technology. Recent developments could in fact have emphasized the existence of risks that were not identified in the past, and could have provided new solutions. For this reason, risk management should never be considered completed and concluded; on the contrary, the employer should periodically review the procedures in place and the materials and equipment in use within the organization and examine the opportunity or necessity to change them with less harmful ones.

Except for particularly dangerous materials and activities, the law does not prescribe how to manage occupational risks. In the same way, there are no mandatory provisions establishing to what extent employees can be considered protected from hazards. It is the employer's responsibility to evaluate this and decide how to proceed, also bearing in mind the measures that have already been implemented within the company. If those measures do not appear appropriate, they must be strengthened; alternatively, new ones must be introduced.

In each company, the pursued level of prevention and protection depends on the dominating risk philosophy (Bosetti 2015). If the board of directors in large companies or the employer in small ones are particularly averse to taking risks, the health and safety risk management system will probably include training of personnel and

pervasive controls to eliminate or reduce the hazards, in the best interest of the workers. Moreover, the commitment to health and safety shown by the board or the employer can encourage all the personnel to pay attention while performing their tasks, so that dangerous conducts can be avoided; indeed, workers must take reasonable care of their own and their colleagues' health and safety.

The whole process of occupational risk management can deliver better outcomes for both the workers and the employer if it is carried out through a collaborative approach between the parties. Consultation and involvement of employees is indeed fundamental for the employer to acquire better knowledge and understanding of all the workplace hazards. As employees are directly exposed to the hazards, even on a daily basis, their suggestions can add value to the whole process. Experts in health and safety issues with background and experience in the specific industry of the company should also be engaged in the process. Similarly, other employers, managers, entrepreneur associations, and trade unions can provide important insights toward a healthier and safer workplace.

According to the European Agency for Safety and Health at Work (EU-OSHA 2007), occupational risk management should take place as shown in Fig. 1, irrespective of the company's size and activity.

Collection of the Information Necessary for Implementing Occupational Risk Management

The process starts with the collection of information concerning the workplace, the activities carried out and all the different types of workers operating not also in the company's premises, but also elsewhere (e.g., drivers who spend their working day on the road and salesmen who visit clients' offices and customers' homes). In-depth knowledge and understanding of the company's structures, processes, and personnel composition is essential to identify the occupational hazards and determine whether preventive and protective measures are needed. The employer should, *inter alia*, collect information regarding:

Health and Safety,

Fig. 1 Steps in occupational risk management. This figure shows the five steps for implementing effective processes of occupational risk management within an organization of any size and industry. Created by this Author, based on EU-OSHA (2007)

- The workplace layout. For example, is there enough space to walk from a workstation to another without being hit by pieces of machinery or furniture? Is the workstation organized in such a way as to be comfortable for the workers, or are they compelled to do unnatural movements to reach and use the working tools? Are there bare electrical wires in the workshops or in the offices?
- The equipment, tools, and materials used. For example, does the equipment contain sharp and protruding parts? Do the processes employ chemicals that could provoke burns, or do they release toxic gases?
- The jobs performed. For example, what risks to health and safety can be associated to the activity of a glassmaker, a carpenter, a building constructor, a bank clerk, a secretary, a teacher, a driver, a lab researcher, a nurse, a surgeon, and so on? Obviously, every job entails exposure to peculiar hazards. Moreover, in a company several different jobs are normally performed, such as manual and administrative jobs. This requires careful observation of each position included in the company's organizational chart, in order to identify the possible sources of injury and illness for each of the jobs performed in the company.
- The composition of the personnel, with focus on so-called vulnerable workers. For example, are there new or expectant mothers, agency and temporary workers, new or young workers, migrant workers, homeworkers and lone workers, or people with disabilities or illnesses? Workers belonging to these categories are often exposed to specific risks, which require greater attention in the process of occupational risk management. Table 1 provides some examples.
- The hazards identified in the past and the measures already in place to deal with them.
- The accidents, near misses, and cases of occupational diseases occurred to the company's personnel or in the company's sector in the past.
- The latest scientific and technological studies pinpointing new and emerging risks and those suggesting more advanced solutions for already known risks.
- The evolution of health and safety laws, with emphasis on the new requirements introduced.

This wide range of information can be obtained from a number of sources: direct observation of the workplace, the activities and the personnel, employee interviews, technical data on the equipment and materials used in the production, reports on occupational accidents and diseases occurred in the company or the sector, studies on the effects

Health and Safety, Table 1 Vulnerable workers and protection needs

Vulnerable workers	Reasons for additional care in protecting vulnerable workers' health and safety
New or expectant mothers	They cannot lift or carry heavy loads; they need rest; they cannot be exposed to biological and chemical agents; they are more exposed to work-related stress.
Agency and temporary workers	They could have little experience with the assigned tasks; they could have limited knowledge of how machines operate.
New and young workers	They could have little experience with the assigned tasks; they could have limited knowledge of how machines operate. As specifically regards young workers, they often have little awareness of existing and potential risks, also due to lack of maturity.
Migrant workers	They could have little experience with the assigned tasks; if they do not speak the same language of the employer and the other employees, they could have difficulties in understanding instructions on how to perform the activities and how to deal with hazards.
Homeworkers	As they perform activities such as, e.g., working with adhesives and soldering, at their own home, they are not constantly monitored and this could lead them to put little attention in the operations, with higher risk for their health and safety.
Lone workers (e.g., construction workers, salesmen, truck drivers, and home care nurses)	Working without direct supervision could expose them to verbal or physical violence. Working in isolation can affect their social life.
People with disabilities or illnesses	They could need reasonable adjustments of the workplace, including extra equipment and changes to layout in order to overcome physical barriers.

Created by this Author, based on HSE (2014)

of pollutants released by the company's industrial processes, and other scientific and technical publications.

Hazard Identification

Once the information has been collected, the employer must use it to identify what hazards really exist in the company. Many hazards are job-based and sector-based (see examples in Table 2), whereas others can be found in any organization.

The most common hazards are associated with slippery surfaces, hot and cold materials, micro-climate (temperature, sun radiation, humidity, and airflow), noise, electrical lighting, sitting in a poor posture, moving machines, working on ladders, lifting loads, handling tools, driving in the traffic, etc. Some other hazards are related to the organization of the work, regardless the company's activity or sector: for example, night and early morning shifts can alter the sleep and make it

difficult to have a normal social life. Hazards also include violence at work, such as verbal abuse, threats, mobbing, and psychological hazards.

A psychological hazard many employees are exposed to is work-related stress (Health and Safety Authority 2011; Biron et al. 2012), i.e., excess of pressure at work or pressure that lasts for a long time. Stressed employees perceive the work environment as too demanding compared to their ability to cope. Sometimes, stressed workers desire larger autonomy and more prestigious assignments, and the impossibility to reach these objectives increases their feeling of frustration. Work-related stress has psychological, physical, behavioral, and organizational implications. It can seriously put the employee's health at risk, because it can influence his or her psychological status, even leading to depression, and provoke physical discomfort, disorders, and illnesses. In addition to this, work-related stress can affect the

Health and Safety, Table 2 Examples of activity-based and sector-based hazards

Activity or sector	Hazards
Office work	Slips and trips; obstacles on the route; microclimate; noise; posture; computers and screens; wires and cables; office equipment (chair stability, arm and foot supports, etc.); continuous work in front of the screen; problems with eyesight; musculoskeletal pain.
Construction	Falls from heights; trench and scaffold collapse; electric lines; workplace transport; repetitive motion injuries; exposure to dust; failure to use personal protective equipment.
Food preparation, cooking, and service	Slips and trips; obstacles on the route; handling heavy items (flour sacks, pieces of meat, etc.); contact with steam, hot water, hot oil and hot surfaces; handling knives; failures of electrical and gas appliances; contact with chemical cleaning products; drunken customers.
Drycleaners	Use of chemical products and chlorinated solvents; musculoskeletal pain from handling heavy/bulky clothes; burns from ironing; slips and trips; verbal abuse and threatening behavior from customers; failures of electrical appliances.
Call center	Stress due to lack of control on timing/frequency of incoming calls; verbal abuse from customers; noise and overlap of voices; voice loss; poor hygiene of headset; slips and trips; office equipment (chair stability, arm and foot supports, display screen equipment, etc.).

Created by this Author, based on: EU-OSHA (2007); Examples of risk assessment retrieved from the Health and Safety Executive’s website, <http://www.hse.gov.uk>, 4 August 2022

organization’s productivity and climate, especially if stressed workers become careless or slow in performing their tasks and refuse to cooperate with their colleagues.

Risk Assessment

Since risk management is an expensive and time-consuming process, the employer has to prioritize health and safety risks in order to establish which ones require to be managed. The decision depends on the outcomes of risk assessment, which estimates risk likelihood and impact. In this phase, previous experience is useful to establish the likelihood that a specific hazard will materialize and the impact it will produce in terms of employees harmed, types of injuries occurred (fatal or non-fatal ones, with temporary or permanent impairment), and working days lost. Broader considerations should also involve the estimated cost of reputational damage that can follow an accident.

Different qualitative and quantitative techniques (Dougherty 1999; Frame 2003) can be applied to assess occupational risks; however, all of them express risk as a combination of likelihood and impact. For example, the likelihood of a hazard (e.g., falls due to slippery floor) can be low, medium, or high, according to how often that hazard has materialized in the past (e.g., once a week, once a month, once a year); the impact can be null, moderate, medium, or extreme, according to the injuries occurred (e.g., no injury, bruises, broken legs or arms, fractures leading to disability).

Priority will be given to the occupational risks with the highest probability of occurrence and the most severe estimated effects; by contrast, risks with very low probability and limited impact will not require any treatment.

Risk Treatment

When an occupational risk is not tolerable by the company, a risk response is adopted to eliminate it at all or to reduce its probability and/or impact.

At first, the employer should adopt collective protective measures, whose selection should be discussed with the employees directly exposed to the risk or their representatives. In this sense, risks for health and safety may be managed through the modification of work methods, the replacement of dangerous substances (a solution that also reduces the environmental impact of

business processes), a different organization of working time and breaks, building improvements to assure better ventilation, lighting and climate, and so on.

Training is a significant collective measure to protect the health and safety of the personnel. Thanks to the professional skills they have acquired, trained workers know how to use machinery and tools in the correct way and how to carry out dangerous processes. Most of all, trained workers are aware of the risks to which they are exposed, so they are stimulated to remain vigilant in any circumstance. Trained and experienced workers can also serve as mentors for young and newly hired workers; in particular, mentoring is a convenient method for sharing not only skills and competencies, but also a positive health and safety culture (Alli 2008). All of this contributes to the reduction of incidents, with clear benefits for all personnel.

For risks that cannot be eliminated or properly reduced through collective measures, the employer must provide the workers with personal protective equipment (PPE) and teach them how to use it. The employees receive their PPE free of charge and are responsible for its correct usage and conservation. Tables 3 and 4 identify some examples of PPE whose adoption is sometimes

imposed by law: for example, using PPE at work is prescribed in construction and industrial productions that could harm body parts (eyes, head, neck, ears, hands, lungs, etc.).

Risk Reporting

The last step in occupational risk management consists in documenting the process and its outcomes. All the steps must be described in a detailed report, also specifying which people have cooperated with the employer to identify hazards, assess risks, select and implement measures to deal with them, and monitor and review the whole process.

An accurate report should also focus on the risks that have actually occurred. All accidents should be investigated, possibly by independent auditors, to discover their causes and promptly eliminate or contain them. Investigating near misses is also necessary to constantly improve risk prevention within the company.

Risk reporting is important for demonstrating the commitment of the employer to assure adequate health and safety on the workplace, in compliance with the law and in accordance with the expectation of primary stakeholders, such as the personnel, trade unions, and public agencies entrusted with the supervision of occupational issues.

H

Health and Safety, Table 3 Personal protective equipment to prevent body injuries

Parts of the body requiring protection	Hazards	Examples of personal protective equipment (PPE)
Eyes	Chemical splash; dust; gas; bright and glaring light	Safety spectacles and goggles; face screens; visors
Head and neck	Impact from falling or flying objects; hair caught in machinery	Safety helmets; hairnets; welding masks; sanitary bonnets
Ears	Noise	Earplugs; earmuffs
Hands and arms	Abrasion; hot and cold temperatures; cuts and punctures; chemical splash	Gloves; sleeves; cotton gloves; anti-vibration gloves
Feet and legs	Wet, hot, and cold conditions; slipping; cuts and punctures; chemical splash	Safety boots; safety shoes; water resistant boots; knee-pads
Lungs	Dust; gas; oxygen-deficient atmospheres	Filtering face masks; disposable masks; respirators
Whole body	Heat; chemical splash; contaminated dust	Overalls; aprons; disposable clothing

Health and Safety, Table 4 Personal protective equipment and emergency equipment to be used in particular circumstances

Circumstance	Hazards	Examples of personal protective equipment (PPE) or emergency equipment
Working at height	Falls	Safety harnesses and ropes; non-slip outsole with cleats and other safety footwear
Roadworks	Collisions and risk of being run over	Flags; warning barrier tape; traffic control chain; mobile traffic signs
Fire protection	Burns; breathing problems	Smoke detectors; fire sprinklers; fire extinguishers; fire hoses; respirators
First aid	Worsening of the sick or injured person	First aid kit; traditional and aluminum emergency blankets; stretchers; resuscitation equipment and defibrillator

Created by this Author

Summary

The evolution of the business environment requires a rethinking of health and safety risk management. Nowadays, the traditional “zero-harm” approach is no longer sufficient; instead, companies should implement a pro-active approach, based on the awareness that health and safety risk management can be a powerful means of value creation in the long term. This is also consistent with the sustainable approach promoted by the 2030 Agenda, which calls for a sound integration of business prosperity, people’s well-being, and low environmental impact.

In this regard, involvement and consultation of employees has a broader scope than mere compliance with the law. Employees’ involvement should be interpreted as a form of stakeholders’ engagement, which tends toward wider purposes: not only the identification of occupational hazards and the selection of preventive measures, but also the factual recognition that employees deserve to take part in corporate decision-making, since they play a key role in the company’s sustainable success. Moreover, it has been largely proved that employees’ engagement increases workers’ motivation and loyalty to the company, with a positive impact on productivity, quality of work and corporate financial performance.

The modernization of occupational health and safety also requires to enlarge its focus in order to include emerging psychosocial risks like bullying and harassment. The comprehensive wellness of each worker should therefore constitute the final

aim and main care of occupational risk management, which should also be integrated with quality management systems.

However, the effective adoption of a more responsible approach depends on the full determination of the company’s leadership. Strong commitment toward a more participative governance is indeed crucial to face the new challenges of occupational health and safety.

Healthcare Value

Carmela Gulluscio

[Health value](#); [Value in healthcare](#)

Definition

Healthcare value has been defined as “the satisfaction of expressed and latent health needs of single individuals and of the community, respecting the objectives established by health planning (at national level, regional level, etc.), timely, in comfort conditions, without waste of resources, maintaining the conditions of economic and financial balance, with the parallel social balance, enhancing the intellectual capital and guaranteeing the knowledge development and improvement in the medical and health sector” (Gulluscio 2011, 2013).

This definition focuses first and foremost on public health organizations, describing the process of generating and distributing value performed by public and private health institutions, notwithstanding in which welfare state model they operate.

Introduction

The supply of healthcare services has great social relevance. It is therefore connected with

sustainability and social responsibility issues. In fact, health is one of the most relevant needs of human being and of the entire administered community. Health services can be supplied by public administrations, private organizations, or by a combination of them.

The concept of value is very relevant for public and private, profit and nonprofit organizations since all of them pursue the common goal of creating and distributing value among their stakeholders. To create value just for one category of stakeholders is not enough; organizations improve their survival probability over time meeting the needs of several stakeholders. This happens through the creation and distribution of value to the various stakeholders of the organization.

It is therefore interesting to identify and analyze the characteristics of the value that healthcare organizations (especially those operating in the public sector) should produce and distribute. This value will henceforth be referred to as “healthcare value.” The production and fair distribution of this value is the main goal that all healthcare organizations should pursue.

In this introduction, the most relevant definitions of healthcare value are presented. The following section is devoted to an in-depth analysis of the definition here proposed.

According to Porter and Teisberg (2006), healthcare value is “the patient outcomes per dollar spent.” Three main aspects emerge from this definition:

- (a) Value is here interpreted under a specific point of view, i.e., in the patient’s perspective. In fact, the patient can be understood as the most important stakeholder in the value production process.
- (b) In the process of healthcare value creation, it is important to consider the outputs (i.e., the amount of services provided) and the inputs, but the most relevant element to be considered is the outcome in terms of patient’s health.
- (c) The value creation process can be synthesized through the “value equation,” i.e.,

Outcome (actual results of care in terms of patients’ health) cost.

At the numerator, the outcome is a multi-dimensional data, incorporating the satisfaction felt by patients, such as survival, the sustainability of the recovery, and functional status.

At the denominator, cost includes the expenses related to a specific care occurrence for a single patient and also total costs connected to the whole care cycle for each patient’s medical state.

According to Fielden (2011), healthcare value can be understood as “useful outcomes divided by the cost of achieving those outcomes.” Even in this definition, the most relevant aspect of value is the improvement of patients’ health.

According to AQA Alliance (2006), healthcare value is “a measure of specified stakeholder’s (such as an individual patient’s, consumer organization’s, payer’s, provider’s, government’s, or society’s) preference-weighted assessment of a particular combination of quality and cost of care performance.” In this case, the perspective of value seems to be broader than in previous definitions, since it is interpreted in a multi-stakeholder point of view instead of in the simple patient’s perspective. Moreover, this definition has a subjective focus, as it emphasizes the valuations and preferences of a specific stakeholder. There are also relevant points in common between this definition and the previous definitions of healthcare value. In fact, similarly to previous definitions, according to AQA, healthcare value is the end result of a couple of elements: costs and care quality.

AQA’s definition is the starting basis for Chung et al. (2008)’s definition, according to which “healthcare value is a measure of a stakeholder’s utility for a particular combination of quality and output.” In this definition, the main element emerging is the notion of “utility.” Healthcare value is therefore interpreted as a metric for evaluating stakeholder’s utility, i.e., the well-being (or contentment) that a stakeholder using a healthcare service perceives. The authors suggest to measure this value through the stakeholder’s willingness to pay for the service. This definition focuses on the relationship between quality and

output. It differs from AQA's definition since the latter focuses on the relationship between quality and cost.

Muir Gray (2011) analyzed the notion of healthcare value has been widely analyzed by, specifying that it can be explored from distinct stakeholders' perspectives, i.e.:

- (a) In the *payer's* standpoint: the maximization of value is reached if it is not possible to raise the good or to reduce the bad reallocating a single euro from one group of patients to another or from one place to another.
- (b) In the *patient's* standpoint, healthcare value depends on both the *outcome* and the *way of delivering the care*.
- (c) In the *clinician's* standpoint, healthcare value is maximized when his/her time is profitably employed since the scarcest resource for clinicians is their time.
- (d) In the *manager's* standpoint, the maximization of healthcare value is reached when it is possible to offer health services maximizing satisfaction and minimizing disbenefits, gathering the needs of financiers and persistently ameliorating the standing of service.

According to Muir Gray, healthcare value is maximized with the achievement of *optimality*, i.e., the balance between costs and benefits of healthy activities.

The definitions presented in this section predominantly zoom in on the relationship between costs and benefits/utilities. Save Muir Gray, all of them consider a single stakeholder at a time.

The following section analyzes the multi-stakeholder definition presented at the beginning of this contribution, inspecting its single elements.

Meaning of the Concept of Healthcare Value

The definition of healthcare value here proposed considers it as "*the satisfaction of expressed and latent health needs of single individuals and of the community, respecting the objectives established by health planning (national, regional, etc.)*,

timely, in comfort conditions, without waste of resources, maintaining the conditions of economic and financial balance, with the parallel social balance, enhancing the intellectual capital and guaranteeing the knowledge development and improvement in medical and health sector."

Like Muir Gray's definition (and differently from other definitions reported in the introduction of this contribution), this definition is manifold, taking into account various stakeholders and needs to fulfill. The main elements of this definition will be analyzed in the following.

First of all, the definition relates to *health needs*. According to the World Health Organization (WHO), health is a state of physical, psychic, and social well-being, and not the simple absence of sickness or infirmity. The interventions in support of health can be extremely broad: prevention, diagnosis, care, rehabilitation, etc. Moreover, healthcare services are sometimes collective services, i.e., services where the individual share of use cannot be or can difficultly be identified (e.g., in prevention and hygiene).

The proposed definition also refers to *expressed* and *latent* health needs. In the case of *expressed* health needs, health administrations must deliver services according to specific users' requests. In the case of *latent* health needs, health administrations must deliver services not specifically requested by any user, but useful to play a part in the whole enhancement of the community's health status, e.g., in the case of preventive screening.

The definition also mentions the "*respect of the objectives established by public health planning (at national, regional, etc. level)*." Implicit in this part of the definition is the reference to the achievement of *internal effectiveness*.

The satisfaction of health needs should also happen in *timely* and *comfort conditions*. This means that *external effectiveness* should be achieved, delivering services in quality conditions (with patient and caregiver-friendly services, in welcoming and accessible structures, etc.).

The definition also refers to the *absence of resources' waste*, i.e., in *efficiency* conditions.

Moreover, the ability of health administrations to durably operate and survive over time needs the

achievement of *economic and financial equilibrium*, which are conditions emerging from financial statement data.

Anyway, economic and financial equilibrium is not enough to guarantee the health organization's survival. It is also necessary to achieve the *social balance*, understood as a condition in which the general public assigns higher utility to health performances as compared to the resources (like taxes, prescription charges, etc.) necessary to supply the health services.

Reference is also made to an *organizational environment* encouraging the fulfillment of *intellectual capital's* expectancy. In health care organizations, this condition is very relevant, since the connection with patients is essential not only for the performances' effectiveness but also for the patients' felt quality.

The definition also refers to "*knowledge development and improvement in the medical and health sector.*" In other words, healthcare organizations should be able to enhance knowledge, competences, and skills, to promote *progress in the medical and health field*. This happens through research and development of scientific, technical, and medical knowledge, which allow an improvement of care and health conditions for single citizens and the whole community. Healthcare organizations can contribute to scientific, technical, and medical knowledge improvement in two main ways:

- (a) *Directly*, i.e., promoting *research* activity. This usually happens for university hospitals and other structures devoted to research.
- (b) *Indirectly*, i.e., through informing and personnel retraining on research outcomes of other institutions.

Key Issues

There is no single definition of healthcare value. Many definitions focus on the balance between costs and utilities of health services. Other concentrate on the relationship between costs and benefits. In many cases, the focus is on a single

stakeholder at a time. Among the many healthcare stakeholders, most definitions focus on the *patient*, probably because he/she can be considered as the *privileged stakeholder*, i.e., the stakeholder whose satisfaction allows approximately to satisfy also the needs of all other stakeholders.

There are various stakeholders interested in healthcare services, and their needs sometimes conflict. This is why some definitions of healthcare value adopt a multi-stakeholder perspective.

The most relevant stakeholders of healthcare organizations are:

- Citizens
- Health and non-health personnel
- Other public administrations
- Suppliers
- Research centers and universities
- Professional associations
- Trade unions
- Volunteers' associations
- Media

Summary

Healthcare value literature should focus, in the future, to the analysis of the different stakeholders' expectations and, therefore, should provide multi-stakeholder interpretations and definitions.

Prospects for healthcare value literature include the measurement of this value (see Porter 2010). In fact, given the complexity and multidimensionality of healthcare value, its measurement is quite complicated. Whereas inputs (e.g., the purchase cost of production factors) and outputs (e.g., the number of medical checks or surgeries) are quite easy to "measure," it is much more complicated to measure the outcomes of healthcare activities (e.g., the consequences of a health treatment on the patient's health conditions). The latter aspect should be the object of future research and application in the practice.

Higgs Report (UK)

Louise Gorman¹ and Anne Marie Ward²

¹Technological University Dublin, Dublin, Ireland

²Ulster Business School, Ulster University, Newtownabbey, Northern Ireland

Description

The *Review of the Role and Effectiveness of Non-Executive Directors* (Higgs 2003), hereafter called the *Higgs Review*, was published in 2003. It is called the *Higgs Review*, after Derek Higgs, the lead author. The review was commissioned by

the UK government to provide an independent assessment of the role and effectiveness of non-executive directors. The terms of reference of the review were to assess the effectiveness and independence of non-executive directors; the extent to which they delivered accountability to shareholders; issues related to their remuneration; the role of the *Combined Code*; and potential means of strengthening independence.

The *Higgs Review* offers guidance to non-executive directors and the chairman and sets out a wide-ranging set of suggested amendments to the provisions of the *Combined Code*. The chapter begins by setting the background to the review. Then its guidance and recommendations are reviewed. The entry concludes with an assessment of the impact of the review.

Background

At the turn of the century, accounting failures and collapses of major US firms, such as WorldCom and Enron, caused global policy makers to turn their spotlight to corporate governance. In the USA a prescriptive rules-based approach resulted. The New York Stock Exchange amended its rules, and the Securities and Exchanges Commission enacted corporate governance legislation through the Sarbanes-Oxley Act, 2002. The scandals also caused policy makers across the globe to review their approach to corporate governance. The Financial Reporting Council led an investigation into *Developing the Guidance on Audit Committees* (the *Smith Report*) which was published in 2003, and the UK government commissioned an independent review of the role and effectiveness of non-executive directors led by Derek Higgs. As a result of this review, the UK government continued to refrain from introducing strict legislation on corporate governance. Instead the *Higgs Review* proposed changes to the *Combined Code on Corporate Governance* (1998) (hereinafter the *Code*) particularly with regard to (1) the role of the board; (2) the role of the chairman; (3) the role of non-executive directors; (4) the role of a senior independent non-executive director; (5) board effectiveness; (6) recruitment and appointments

to the board; (7) induction, development, evaluation, and the supply of information to non-executive directors; (8) terms of engagement; (9) the audit and remuneration committees; (10) the liability of non-executive directors; (11) and shareholder relations. The key recommendations are now outlined.

The Role of the Board

The UK government's commissioned review of the role and effective of non-executive directors coincided their reform initiative to modernize company law. At this time there was a burgeoning view, reflected in academic literature and by policy makers, that a focus by directors on shareholder value may be detrimental to other stakeholders and society at large (Armour et al. 2003; UK House of Commons Trade and Industry Committee 2003). Therefore, the appraisal considered directors' duties to promote the success of the corporate for the benefit of its shareholders while taking account of the need to foster relationships with employees, suppliers, customers, communities, and the environment. Consistent with the government's work in this regard, the *Higgs Review* does not refer to the primacy of shareholders but suggests the *Code* simply states that "the board is collectively responsible for promoting the success of the company by directing and supervising the company's affairs" (suggested principle A1). This is a move away from shareholder wealth maximization as inferred in the *Hampel Report* toward corporate sustainability. The *Review* takes the view that the success of the corporate is the primary objective that directors should be pursuing. This objective is usually congruent with shareholder wealth maximization; however, it encourages directors to take a long-term view in their decision-making. The provisions suggested in principle A1 recommend that the annual report include a description of how the board operates, distinguishing between decisions taken by the board and those taken by management and detailing the number of and attendance at board and committee meetings. The effective functioning of very large and small boards is

questioned, and the review recommends reducing board size (para 4.9). The *Review* stops short of proposing specific recommendations on board size, suggesting “an effective board should not be so large as to become unwieldy. It should be of sufficient size that the balance of skills and experience is appropriate for the requirement of the business and that changes in the board’s composition can be managed without undue disruption” (suggested provision A.3.1).

The Role of the Chairman

The *Higgs Review* found a splitting of the roles of CEO and chairman in almost 90% of listed corporates. This initiative was first recommended by the *Cadbury Report* (1992) and later reaffirmed by the *Hampel Report* (Hampel Committee on Corporate Governance 1998) and subsequent *Combined Codes*. Given that the benefits of separation are widely acknowledged (para 5.3), the *Higgs Review* continues with the recommendations of Cadbury and Hampel by recommending that the roles of the CEO and chairman should be separated if not already done so (suggested provision A.2.1).

The Role of Non-executive Directors

While not recommending that a legal distinction between the responsibilities of executive and non-executive directors is required, the *Higgs Review* recommends that the *Combined Code* should provide a description of the role of non-executive directors. In general, the *Higgs Review* advises that non-executive directors should support executive directors in their leadership of the business and should monitor their conduct (para 6.6). In terms of specific areas of duty and responsibility, the *Higgs Review* suggests that non-executives should contribute to strategy; monitor the performance of management; be satisfied with the reliability of financial information and the adequacy of financial controls and systems for managing risk; take responsibility for the remuneration, appointment, and removal of executives and take

a prime role in the appointment, remuneration, and removal of management and in succession planning (suggested provision A.1.4).

In addition, to defining their role, the *Higgs Review* also recommends that non-executive directors meet as a group, on their own, at least once a year, and compliance with this recommendation should be reported in the annual report. Finally, the *Higgs Review* puts the onus on non-executives to ensure that they have the knowledge, experience, and time to make a positive contribution to the board of directors. It is recommended that the prospective non-executive examines the existing board when evaluating whether they can make a positive contribution to the board.

The Senior Independent Non-executive Director

The recommendation that the board has a senior independent non-executive director that serves as a link between major shareholders and the board is strongly supported in the *Higgs Review* (para 7.5). To support this, the *Higgs Review* suggests that the nature of the role be clarified. In particular, it recommends that the senior independent non-executive director be available to address any shareholder concerns that cannot be resolved by contact with the chairman or CEO (suggested provision A.3.6). It is also recommended that the senior independent non-executive director chairs meetings of non-executive directors when the chairman cannot be in attendance (suggested provision A.1.5).

Board Effectiveness

The *Higgs Review* recognizes the need for an effective supply of timely, corporate-specific information to the board which can be best achieved through an executive presence. It is thus suggested that the *Combined Code* clarifies the need for balance by stressing the importance of strong executive representation on the board (suggested provision A.3.2). Independent

oversight is also regarded as fundamental to the strength of the board as a corporate governance instrument, particularly with respect to the functioning of the board's committees. Hence, the *Higgs Review* recommends that at least one half of the board consist of independent non-executive directors (suggested provision A.3.5). This goes further than the *Combined Code* that recommended that not less than one third of the directors should be non-executive. The potentially valuable contribution made by non-executive directors affiliated with the corporate is acknowledged and executive directors should take care not to preclude their inclusion on the board (para 9.6). Consistent with the statutory position taken in the UK, the review suggests that directors' decisions ought to be taken objectively within the interests of the corporate (suggested provision A.3.3).

In terms of non-executive directors, it is recommended that a definition of independence be included to reduce ambiguity surrounding the term. The *Higgs Review* suggests that a non-executive director is independent when the board considers that he/she is independent in character and judgment. Moreover, relationships and circumstances deemed both to effectively and potentially impair a director's objectivity are outlined (suggested provision A.3.4). In particular, a non-executive director may not be considered independent if he/she has been an employee of the corporate within the last 5 years; has had a material business relationship with the corporate within the last 3 years; receives remuneration from the corporate beyond the non-executive director's fee; has close family ties or cross-directorships; is a significant shareholder; or has served on the board for more than 10 years. Finally, the *Higgs Review* recommends disclosure of all independent non-executive directors in its annual report.

Recruitment and Appointment

The *Higgs Review* sets a vision of *meritocracy in the boardroom* (para 10.8) which requires a range of skills and attributes acquired through a diversity of experiences and backgrounds suited to

meet the changing needs of the business (para 10.1). To achieve this, the *Higgs Review* recommends that all boards have a nomination committee. This extends the requirement in the *Combined Code* that recommended this practice when boards are not small. The nomination committee's role in maintaining the appropriate board composition is linked to its independence of judgment, and hence, it is suggested that it comprise a majority of "independent" non-executive directors and be chaired by an "independent" non-executive director (suggested provision A.4.1). It goes further than the *Combined Code* at the time, which did not refer to the need for independence on the nomination committee.

Of concern to the Higgs's research team was the "high level of informality" surrounding the processes used to appoint non-executive directors. The *Higgs Review* notes that this lack of formality could be detrimental and "lead to an overly familiar atmosphere in the boardroom." To address the potential problem, the review recommends that formal recruitment policies be designed that include an evaluation of the skills, knowledge, and experience required from the candidate as a crucial prerequisite (suggested provision A.4.3). It is recommended that the nomination committee's work in this respect be disclosed in the annual report, indicating the nature of external advice or open advertising used or an explanation as to the lack thereof (suggested provision A.4.10). Disclosure in the annual report of the activity of the nomination more generally is also deemed necessary. Specifically, it is suggested that the number of committee meetings held and the level of attendance at each be stated (suggested provision A.1.2). The *Higgs Review* also designated responsibility to the nominations committee to ensure that prospective non-executive appointees to the board are made aware of the commitment expected of them in terms of time, committee membership, and involvement outside of board meetings (suggested provision A.4.4). When investigating the role of non-executive directors, Higgs found that lack of time commitment was one of the main criticisms made of non-executive directors. Transparency to shareholders is emphasized, and it is recommended that the

board explains to shareholders the justification for each appointment (suggested provision A.4.5). The *Higgs Review* found little evidence of succession planning and suggested that the nominations committee be able to satisfy itself that a framework is in place to support orderly succession to maintain an appropriate balance of skills on the board (suggested provision A.4.9).

Induction, Development, Evaluation, and the Supply of Information to Non-executive Directors

The *Higgs Review* points out that the value of skills, knowledge, and experience relies upon a director's awareness of where they may be applied. Thus, the provision of a formal, comprehensive and tailored induction to new non-executive directors is deemed necessary (suggested provision A.5.6). With regard to the maintenance of a suitable balance of skills and knowledge on the board, the review suggests that an annual performance appraisal should be conducted by means of assurance that the board remains fit for purpose (suggested provision A.6.1). Consistent with the general promotion in the *Higgs Review* of transparency, it is recommended that the performance of such an appraisal and the manner in which it is conducted should be disclosed in the annual report (suggested provision A.6.2). In addition, the *Higgs Review* recommends that the chairman, supported by the corporate secretary, should assess the information needs of the board. The executive directors should prepare a report on these information needs and be prepared to verify its accuracy, reliability, and compliance with the law and relevant standards (suggested provision A.2.5). Equally, non-executive directors have a responsibility to ensure that the information presented to them is of sufficient quality to enable them to perform their duties in, for example, the areas of nomination, remuneration, and audit. They are encouraged to seek clarification if necessary (suggested provision A.5.1). The corporate secretary's role in ensuring good communication is highlighted, and it is recommended that they be accountable to the

board through the chairman on all governance matters (suggested provision A.5.2).

Terms of Engagement

Consistent with recommendations emerging from parallel work conducted in the government's Company Law Review, the *Higgs Review* proposes that the *Combined Code* recommends disclosure of non-executive directors' terms of engagement (suggested provision A.4.11). The *Higgs Review* notes the potential for annual reelection of directors to promote a culture of short-termism and suggests that non-executive directors should normally be expected to serve two 3-year terms with the corporate. It is acknowledged that longer service may be justified for directors who add particular value to the board, but only as an exception which should be explained to shareholders (suggested provision A.7.3). Reelection is deemed appropriate after 9 years for non-executive directors (suggested provision A.7.3). The *Higgs Review* also recommends that limits be included in the *Combined Code* on the number of non-executive director roles an executive director can hold. Specifically, the review recommends that full-time executive directors should only take on one non-executive directorship and should not become chairman of a FTSE 100 corporate. Moreover, no individual should be chairman of more than one FTSE 100 corporate. This recommendation caused much controversy as many executive directors held several roles on the boards of other corporates. In addition, the recommendations made no reference to limits on the number of roles a non-executive director could hold.

In terms of the remuneration of non-executive directors, the *Higgs Review* endorses payment on the basis of fixed fees, for example, an annual fee and meeting attendance fees. The *Higgs Review* considers the benefits and drawbacks to the holding of shares by non-executive directors and acknowledges that an ownership stake may serve to align their interests with those of shareholders but stresses the potential that the granting of share options as an element of non-executive director

remuneration may encourage an undesirable focus by non-executive directors on share price rather than on underlying corporate performance. Hence such a practice is discouraged (suggested provision B.1.7). However, payment in shares instead of being paid by cash is endorsed so long as the non-executive director's shareholding does not represent a large proportion of his wealth. Resignation by directors in circumstances where the director has critical concerns with the running or actions of the board is viewed as an option of last resort. In such circumstances, it is recommended that the director informs the chairman in writing of his resignation accompanied by an explanation for the decision to do so such that it may be circulated to all board members (suggested provision A.1.6).

The Audit and Remuneration Committees

Mindful of the need to avoid any one individual exerting undue influence over the board's decision-making activities, the *Higgs Review* recommends that no director sit on the nomination, audit, and remuneration committees, concurrently (suggested provision A.3.7). This recommendation does not apply to smaller corporations. The review does not dwell upon the role of the audit committee, rather it endorses the recommendations put forward concurrently by the *Co-ordinating Group on Auditing and Accounting Issues* under Sir Robert Smith (Para 13.7). The composition and role of the remuneration committee is considered. The *Higgs Review* recommends the remuneration committee comprise at least three members and that membership be restricted to independent non-executive directors (suggested provision B.2.1). The responsibilities of the remuneration committee are recommended, at a minimum, to include: setting remuneration for all executive directors and the chairman, including pension rights and any compensation payments, and setting the level and structure of remuneration for senior executives (suggested provision B.2.2). In support of transparency, the

Higgs Review recommends disclosure of the remuneration committee's activity, in terms of meeting frequency and attendance (Suggested Provision A.1.2).

Liability of Non-executive Directors

The review in this area found that potential liability does not appear to deter individuals from assuming board positions. Consideration is given to the need to provide directors and officers with limited liability insurance. Insurance is a basic protection for non-executive directors against law suits by third parties. By providing insurance, corporates may avoid the need to indemnify directors against such law suits (para 14.19). Hence, it is suggested that the *Combined Code* should refer to this need (suggested provision A.1.7). Guidance for corporates on the exact nature of the insurance which should be provided to directors by the City of London Law Society, the Institute of Chartered Secretaries and Administrators, the Association of British Insurers, and the British Insurance Brokers Association is welcomed in the *Higgs Review*. The review recommends that corporates should supply details of their insurance cover to potential non-executive directors, before they are appointed.

Relationships with Shareholders

Consistent with the *Hampel Report*, the *Higgs Review* advocates dialogue between directors and shareholders at the annual general meeting, in relation to issues concerning their roles (suggested provision C.2.3). The *Higgs Review* proposes that the senior independent non-executive director regularly attend meetings of management with major shareholders to develop an understanding of shareholders' concerns. The senior independent non-executive director should then communicate key concerns back to the other non-executive directors and the full board as appropriate (suggested provision C.1.2). However, this recommendation does not preclude

non-executive directors from attending such meetings. The review recommends that meetings with major shareholders be included as part of non-executive directors' induction (suggested provision C.1.3). The *Higgs Review* endorses the financial community's use of the *Institutional Shareholders' Committee Code of Activism*, which outlines best practice for institutional investors to promote their members' interests through more active engagement as shareholders (suggested provision E.2.1). It also opines that attendance by institutional shareholders' at AGMs where practicable be recommended in the *Combined Code* (suggested provision E.1.4).

Summary

The *Higgs Review* addresses the role of non-executive directors and the issue of independence with considerable rigor. It ought to be commended for its treatment of the issues of induction and development of, and supply of information to, non-executive directors – an area which arguably required deeper consideration than what had previously been conducted by predecessors. Indeed, the review's attention to board processes is regarded as one of its strengths, a welcomed nuance at a time when much consideration of the board's role converged upon financial accountability (McNulty et al. 2005). There is still an emphasis on shareholders as the key stakeholders, as little reference is made to other stakeholders in the review. However, it can be argued that such focus was beyond the scope of the terms of reference of the review. Critics view the recommendation to appoint a senior independent non-executive director as potentially encouraging a concentration of excessive power at the top of the corporate (Aguilera 2005). Yet this is a role which, over the years to follow, received increasing recognition in public corporates and in codes of best practice alike. The advice put forward in both the *Higgs Review* and the *Smith Report* was incorporated into the revised *Combined Code* (2006), much of which was retained in the Financial Reporting Council's Guidance on Board

effectiveness accompanying *UK Corporate Governance Code* (2010), the guidance which replaced the *Combined Code* in 2010 as revised biennially thereafter.

Holistic Development

Mara Del Baldo

Definition

Holistic development is based on alternative assumptions contrasting with the neoclassical *homo oeconomicus* model and is focused on the ends, rather than only the means, of economic interactions.

Holistic development provides a philosophical people-centered understanding of how socio-economic systems and organizations should work to foster human beings and allow them to thrive. Conceptual tools for implementing this vision compel a set of anthropological assumptions and a peculiar relation between humanistic and technical knowledge (Sen 1988).

In recent decades this paradigm – that involves economic, ethical, environmental, and social dimensions – has been put to use in companies' business models. Furthermore, it has been connected to the notion of sustainable development (Elkington 1994). When implemented in managing and governing a business, holistic development is built on a system of moral values, which are person-centered and anthropologically based, incorporated and promoted by the managers, entrepreneurs, and company stakeholders (Argiolas 2006). Indeed, it is multidimensional in nature and aimed at creating shared value triggered by purpose-driven firms (Cohen and Warwick 2006; Carrol 2000; Del Baldo 2015).

Introduction

The need for caring of our 'common home' lies at the core of the international political, scientific, and managerial debate. A renewed environmental, economic, and social ecology capable of integrating concerns for people and the planet requires a collective contribution to the common good and presupposes responsibility people and organizations have in regard to a multi-dimensional development. In this vein, businesses are called to contribute to achieve holistic development, linking the competitive, social, ethical, and environmental dimensions (Sorci 2007) and pursuing a socio-competitive synthesis (Molteni 2004). From the viewpoint of holistic development, each business choice and action manifests an orientation responsive to the consequences of choices on stakeholders, including the socio-economic and environmental system in which the company is embedded. Several studies have pointed out that a holistic

perspective on development is necessary to overcome poverty, inequality, and environmental degradation across the globe (Bebbington 2007; Bouckaert et al. 2007; Ketola 2008; Zsolnai 2015). This need has also been emphasized by the Encyclical Letter *Laudato Si* (Pope Francis 2015) that addressed the integral ecology construct, intended as a renewed environmental, economic, and social ecology that integrates concerns for people and the planet, suggesting a more moderate lifestyle which seeks holistic knowledge and respect for the human and social dimensions of life (Zsolnai 2015). The Encyclical Letter stresses the need for moral-based conduct in daily life, including the business context, called to operationalize fundamental values that have an anthropological connotation (Catturi 2003, Melé 2009 and 2012; Argandoña 2003) and nurture authentic relationships. “There can be no ecology without adequate anthropology” (Pope Benedict XVI 2009; Pope Francis 2015, p. 96).

This urgency also concerns the need to adopt coherent leadership approaches capable of facing the human roots of past and current crisis (Guardini 1998). As Pope Francis pointed out, “We lack leadership capable of striking out on new paths and meeting the needs of the present with concern for all and without prejudice towards coming generations” (Pope Francis 2015: 39). This partly explains the failure of global summits which do not provide proper authentically driven leadership capable of taking the bold decisions necessary in periods of deep crisis.

New institutional and business models capable of incorporating the common good and assuming ethical responsibility (Visser 2011; Del Baldo 2014) are necessary. In past decades the objectives of holistic development have been sidelined, and the idea of unlimited growth has prevailed (Pope Francis 2015). Therefore, a distinctive change, as marked by the sustainable development goals, presupposes a turn toward holistic development.

Transparency and dialogue in decision-making at all levels (micro, meso, and macro level), and a shared orientation toward multi-dimensional development, requires transparency

and dialogue in decision-making and with external stakeholders, particularly at the local level, with local institutions and the community. In this regard, the notion of the territory shifts from an idea of a geographic place to the complex system of tangible and intangible resources historically determined and culturally grounded. The focus is therefore on the network of relations among a plurality of actors, including public institutions, businesses, and civic and not-for-profit organizations, that share common behaviors and values. In other words, the territory’s relational infrastructure represents the social capital that drives virtuous socio-economic and environmental contexts.

Key Issues

To achieve sustainability, a firm has to revitalize its business model (Stubbs and Cocklin 2008; Abdelkafi and Täuscher 2015; Johnson et al. 2008). This implies orienting the company culture, enhancing the leadership model, and strengthening the set of person-centered values and transforming them into business practices. All these changes involve intra- and inter-organizational networks formed by different stakeholders belonging to the wider societal systems (Del Baldo 2016).

A holistic model of business development (Sciarelli 2007) rests on an enlightened stakeholder theory (Jensen 2002) and the stewardship theory (Davis et al. 1997). Both the theoretical frameworks allow for the application of ethical values in corporate choices, such as the principles of solidarity and trustworthiness with stakeholders. Namely, the stewardship theory – founded on sociological traditions – rests on a concept of a human being (i.e., the entrepreneur and the manager) whose decisions are inspired by both economic motivations (extrinsic and tangible) and social and emotive motivations (intrinsic). In the business context, these principles nurture a cohesive governance based on trust oriented to long-term success and to a purpose-driven business model. The need for sustainable

business models has recently gained momentum because many approaches to corporate responsibility have failed to link a firm's sustainability orientation to the core business (Visser 2011), avoiding camouflaged approaches (Bocken et al. 2014; Looser and Wehrmeyer 2015).

Summary

The way in which holistic development can be pursued depends on how sustainable business models are constructed by actors involved in the value creation (Boons and Lüdeke-Freund 2013). In this respect, consistent leadership models (i.e., ethical leadership and responsible leadership) are crucial because entrepreneurs and managers play a key role in shaping the organizational culture and the decision-making process that affect their everyday routine, as well as intra-organization procedures and structures (Melé 2012; Del Baldo 2016).

Ethical leadership rests on personal traits and behaviors such as integrity and transparency in communication with stakeholders (Brown 2005; Capaldi 2013).

Responsible leadership facilitates the involvement of stakeholders and the creation of a cohesive internal and external community cemented by values and moral convictions (Jones 2014). The 'pillars' by which responsible leaders guide the company toward holistic development include stakeholder consideration, communication, empowerment, inclusion, and long-term orientation (Magni and Pennarola 2015).

In summary, holistic development rests on a business model consistent with a leadership model that allows companies to share a strategic orientation toward an integrated development paradigm.

Definition

Hospital governance represents a term relatively complex to define. Indeed, by identifying a process-focused notion, research has recognized the existence of different levels of governance as well as of two main components (Sarto et al. 2014; Saltman et al. 2011). Specifically, literature claims the presence of three levels of hospital governance: macro, meso, and micro. The former is related with the national government decisions influencing and affecting the overall structure of a national health service in terms of financing and number/type of organizations. Differently, the meso (and intermediate) level of hospital governance is concerned with the decision-making at the hospital organizational level and identifies the governing and strategic structures and processes (Eeckloo et al. 2004, 2007). The meso level also deals with the resources allocation needed to reach the strategic goals (Daily et al. 2003; Sarto et al. 2014). Finally, the hospital governance micro level encompasses the operational management of human resources and clinical services. Despite each level presents different characteristics and refers to different individual/institutions responsible of the decision-making, there are a number of interactions among them that are crucial for the functioning of the overall hospital governance system (Saltman et al. 2011). From a different standpoint, literature suggests that the hospital governance involves both the clinical and the economic governance (Kirkpatrick et al. 2014). The former concerns the way in which governing bodies at different levels (meso, micro, and macro) monitor and guarantee the appropriateness and the quality of the care process. The latter includes the monitoring of the financial resources management (Sarto 2015).

Introduction

It is worth noting that the relevance of governance issues in hospitals starts from the recent strong changes that have distinguished the worldwide healthcare sector. Indeed, this setting is facing various problems, such as rising costs, sweeping technology, and rising service expectations

(Bodenheimer and Fernandez 2005). Healthcare organizations are required to respond to the increased need of efficiency and effectiveness as well as to respect the budget constraints (Catuogno et al. 2017). In this regard, the growing costs have determined a debate between equity and efficiency (Erwin et al. 2019). From a different standpoint, healthcare organizations are additionally interested by the increasing demands for greater patient safety and the growing ethical requirements (Hamilton 2008). On the one side, these problems and requirements have been sorted through the introduction of the NPM principles and rules in the provision of healthcare services (Hood 1991). On the other side, they have led to the rise of healthcare regulation requiring a balance between efficiency and effectiveness (Nunes et al. 2007) and a stringent accountability process (Fisher et al. 2007).

As far as our topic is concerned, the above-mentioned challenges have overall highlighted the relevance of governance models (Ford-Eickhoff et al. 2011) and have called the attention of scholars belonging to the governance field toward this kind of organizations (Hamilton 2008; Erwin et al. 2019; Sarto et al. 2014; Bodenheimer and Fernandez 2005). From a practical point of view, all these pressures have led the European countries to introduce a number of measures to face the economic sustainability worries as well as to satisfy citizens' call for greater accountability on the effectiveness and quality of the health services (Kirkpatrick et al. 2013). Indeed, also in light with the assumption of NPM, policy makers have introduced alternative models of hospital governance that, differently from the traditional "professional bureaucracy" (Mintzberg 1979), are influenced by the managerialist ideology (Hood 1991), in the aim to make public hospitals more autonomous, with extended independence in decision-making processes (Aidemark and Lindkvist 2004). These changes have modified the existing institutional structures by introducing, for example, the roles of Chief Executive Officer (CEO) and board of directors (Saltman et al. 2011), recognizing the crucial issue of governance mechanisms in such complex organizations (Sarto et al. 2016).

Hospital Features and Hospital Governance

By focusing the attention on the meso level of hospital governance, it is interesting to explore the role, the composition, and the structure of the governing body (e.g., board of directors). In order to appreciate them, it is worth noting that there exist some hospital features that have influenced its governance issues (Eeckloo et al. 2007). The overall assumption is that hospitals are characterized by a *high stakeholder sensitivity*, that is, the high dependence of such organizations from external and internal stakeholders (Von Nordenflycht 2010).

Indeed, first of all, hospitals are professional service firms (Jarzabkowski and Fenton 2006; Cuccurullo and Lega 2013), whose decision-making process is highly diffused among different internal stakeholders. Indeed, as suggested by Glouberman and Mintzberg (2001), this kind of organization is characterized by the presence of four worlds of actors that determines their high “internal pluralisms”: (a) the world of cure (doctors’ community); (b) the world of care (nurses and other professional workforces around the patient); (c) the world of the administrative hierarchy (managers); and (d) world of the governing bodies (boards). Literature suggests that each category represents different cultural and social contexts, sets of activities and mind-sets (Denis et al. 2001; Sarto et al. 2014).

The high stakeholder sensitivity of such organizations is also amplified by the crucial role played by patients that have experienced an empowerment process. Indeed, over the last decades, patients have become active agents in managing illness and healthcare, by surrendering varying amounts of control to healthcare professionals in order to gain the right expertise, technology, and compassion (Powers and Bendall 2004; Martin 2011).

In addition, the high stakeholder sensitivity depends on the strong knowledge intensity of the healthcare organizations (Von Nordenflycht 2010; Huse 2007). As hospitals are professional services firms, their output relies on a substantial body of complex knowledge embodied in the

individuals (Winch and Schneider 1993). Indeed, the hospital’s main strategic asset is the intellectually skilled workforce that lies not only in hospital executives but also in its frontline workers, such as doctors and nurses (Grant 1996; Von Nordenflycht 2010).

Finally, the high stakeholder sensitivity is determined by the typical ownership status assumed by healthcare organizations. Indeed, most of worldwide hospitals are public-owned organizations, which are characterized by the lack of shareholders who are legally entitled to the residual claims, and where the owners are de facto a larger and diverse set of stakeholders such as tax payers/citizens, patients, GPs, government authorities, and health insurers (Sarto et al. 2014). Due to this phenomenon, healthcare organizations are defined as characterized by high level of “external pluralism” and the emphasis is moved toward the above-mentioned external stakeholders (Von Nordenflycht 2010).

Building on these assumptions, scholars suggest that the high stakeholder sensitivity has required the establishment of a particular configuration of governing body, in terms of *role*, *structure* and *composition* (Capasso and Pascarella 2011; Veronesi and Keasey 2015; Vining and Weimer 2005). For what concerns the role, in the healthcare sector, scholars observe that boards mainly perform the philanthropic and fiduciary role (Kane et al. 2009), as organizations should be oriented to answer the needs of several stakeholders (Del Vecchio 2006). Indeed, in these contexts, the accountability role is crucial and hospital boards are mainly interested in disclosing the effective and efficient achievement of firm strategic objectives, above all in favor of the community (Ramsay and Fulop 2010). Turning the attention to the board structure, research highlights that hospitals should opt for a collegial dualistic model. Indeed, compared to the monocratic one, this kind of governing body allows the inclusion of several stakeholders, with positive implications for decision-making process. Moreover, scholars suggest to prefer the dualistic model rather than the monistic one. Indeed, on the one side, it allows to overcome some coordination problems typical of large teams, on the other side, it supports the separation

of members devoted to managerial and strategic tasks (e.g., executives) from those devoted to accountability activities (e.g., patients) (Sarto et al. 2017). Shifting the focus on board composition, scholars suggest that the high stakeholder sensitivity requires the involvement of several external and internal stakeholders in the governing body (Flannigan and Power 2008). In terms of external actors, literature recommends the involvement of local community members and patients (Veronesi and Keasey 2015), by following the example of the Foundation Trusts that represent a new hospital organizational form in UK (Greenhalgh et al. 2010; Sarto et al. 2014). From a different standpoint, the strong knowledge intensity characterizing hospitals requires a high involvement of knowledge workers in governing body such as doctors and nurses (Flannigan and Power 2008; Sarto and Veronesi 2016).

The Literature on Hospital Governance

A recent literature review has identified the existence of three main research streams in the field of hospital governance: (i) the NHSs governance models, (ii) the board and top management team, and (iii) the role of doctors (Sarto et al. 2014). The first stream is composed by studies investigating the macro level of hospital governance and exploring the characteristics of the governance models employed in different kinds of healthcare organizations of the worldwide NHSs. These articles mainly employ conceptual and qualitative methodologies in order to assess the introduction of those models borrowed from the corporate world (Barnett et al. 2001; Eeckloo et al. 2004). Moreover, these studies investigate how the models have changed over time due to the introduction of new laws and regulations (Gorsky 2008; Stolzenberg 2000; Weil 2003). The second stream of research investigates the meso level of the hospital governance and is composed by articles analysing the board of directors. More specifically, these papers explore this governing body in terms of role (Alexander et al. 2009; Molinari et al. 1993), activities, structure, composition, and processes (Golden and Zajac 2001; Judge and Zeithaml 1992; Young et al. 1992). This

research stream also covers topics such as the CEO-board interface (Alexander et al. 1993; Alexander and Morlock 1985; Brickley et al. 2010; Molinari et al. 1997; Morlock et al. 1985) and the CEO and Top management's compensation and evaluation (Brickley and Van Horn 2002; Molinari et al. 1997). These studies are mainly quantitative and explore the effectiveness of hospital governance structures and the related implications for the organizational performance. Finally, the third and more copious stream of research still concerns the meso level of hospital governance but explores the clinicians' involvement in the hospital governance process. These articles have investigated the performance implications of the doctors and nurses' participation in the governance and management of healthcare organizations (Ham and Dickinson 2008; The King's Fund 2012), by suggesting that greater clinicians' involvement at the strategic decision-making level has several benefits for hospital outcomes.

The Role of Clinical Leadership in Hospital Governance

By focusing the attention on the role of doctors and nurses in governance, the empirical research suggests that the degree of clinicians' involvement in top managerial positions greatly varies across countries. In this regards, some studies document that, in US, clinical CEOs represent only the 4% of total hospital CEOs, and this figure is lower in the present compared to the past (Goodall 2011; Gunderman and Kanter 2009). Similar conclusions are drawn in UK, where board members with clinical background are about 26.03% and clinical CEOs are on average 22% (Veronesi et al. 2013). Different findings are instead reported in continental Europe, as studies document that most of top managers hold a clinical background (e.g., 59% in Italy; 63% in France; 71% in Germany) (Kuntz and Scholtes 2013; Sarto et al. 2019; Dorgan et al. 2010).

Concerning the implications of medical managers' role, literature has mainly suggested that higher doctors and nurses' participation in strategic leadership roles, involves a number of positive

implications for healthcare performance (Jiang et al. 2009; Prybil et al. 2012; The King's Fund 2011; Veronesi et al. 2013, 2014). Indeed, empirical research on clinical leadership has investigated its effects above all on the management of financial resources, the quality of care and the hospital social performance (Sarto and Veronesi 2016). Most of studies belonging to this stream have suggested that greater doctors and nurses' involvement in governance positions may have wider benefits for health services, possibly improving their efficiency, quality, and social performance (Jiang et al. 2009; Prybil et al. 2012; The King's Fund 2011; Veronesi et al. 2013, 2014). Indeed, "in a health care system that is complex, troubled, and challenging," physicians bring "a unique set of skills to the business of medicine" (Falcone and Satiani 2008, p. 88) by providing the organizational management systems with critical advantages. Clinical-managers are better able to interpret the clinical issues and to understand their patients' needs (Lister 2000, 2007). Also, they benefit from an improved communication with medical staff as well as greater credibility, legitimacy and support by the same (Dorgan et al. 2010; Witman et al. 2010). In this sense, healthcare organizations will experience, on the one side, better strategic decisions, on the other side, a higher level of their implementation. Again, prior research has suggested that the medical involvement in directorship positions is frequently established to strengthen clinicians' "commitment to cost containment" (Succi and Alexander 1999, p. 1). This combined with their medical knowledge could determine a better allocation of resources, whose related changes are more easily implemented, thanks to the clinical-managers legitimacy among clinical staff (Molinari et al. 1995; Veronesi et al. 2014). Finally, clinical managers positively influence the hospital social performance due to their ethical beliefs and professional norms (Bai 2013; Bai and Krishnan 2015).

Notwithstanding the positive effects enlightened by the above-mentioned studies, opposite conclusions are provided by a number of articles that have asserted that the involvement of doctors and nurses in governance roles is often counter-productive. Papers belonging to this tradition claim that clinicians' involvement in hospital

governance could have negative implications for the management of financial resources and the hospital social performance due to a number of reasons. First of all, clinicians' participation in the governance processes could determine the emergence of some conflicts among clinicians-turned managers and career managers. Moreover, medical-leaders could experience a role conflict involving decisions made at the expense of financial performance to protect the clinical needs. Additionally, clinical managers could be not able to effectively perform the managerial tasks due to their educational deficiencies in business and accounting areas. Finally, with regard to the social performance, hospital outcomes can be negatively affected by the presence of clinical-managers especially due to the conflict of interests of private doctors in leadership positions (Sarto and Veronesi 2016; Sarto et al. 2019).

Hospital Governing Bodies

► Hospital Governance

Hostile Takeover

Laxmi Remer
CBS International Business School, Cologne,
Germany

Synonyms

Acquisitions (also M&A); Buyout; Corporate raid/raider; Takeover; Unfriendly takeover

Definition

A hostile takeover is when one company, namely, the acquirer buys another company, namely, the target whose management is against the acquisition. Hostile takeovers imply animosity and reluctance. This is usually manifest on part of the target management because in most hostile takeovers, the incumbent management of the target is replaced with a new one.

Hostile takeovers happen when the target management rejects the offer made by the acquirer. The acquirer can then come back with a new offer, in other words, the acquirer can continue to pursue the target.

There are many ways the acquirer can pursue the target, such as,

- Make a *Tender Offer* – here the acquirer makes a fixed price offer which is usually above the market price for the “target” shares.
- Conduct a *Proxy Fight* – here the acquirer approaches the shareholders of the target directly in an attempt to convince them to use their votes to replace the reluctant members of the management with new, more agreeable ones. Here most often, a simple majority of the shareholders is sufficient to vote out the unwilling target management.
- Make a *Creeping Tender Offer* – here the acquirer simply buys shares of the “target” in the market. Once the necessary percentage of shares have been acquired, the acquirer can initiate change in the management of the “target.”

Hostile takeovers are more often seen in countries where the external ownership of the shares is high. External ownership means that a greater number of the issued shares of a company are available for trade in the market, whereas internal ownership is when large chunks of the shares are in the hands of a few shareholders like banks or institutional shareholders. External share ownership therefore allows easier access whereby it is easier to gain control of the target company.

Background

Companies are bought (taken over) for a myriad of reasons. Some such reasons are lateral or vertical expansions, cost reductions, gaining access to different markets or products, competitive strategies, simple consolidations, adding value by restructuring, selling the acquired company piecemeal for profit, etc.

Takeovers have been happening for a very long time. While contested in some circles, Louis Wolfson is considered by many as one who practically developed the idea of market for control by consistently and most times successfully engaging in hostile takeover in the 1940s and 1950s. He seemed to have the knack of identifying undervalued or mismanaged assets and would raid these either by making tender offers or conducting proxy fights. He would then go on to sell these assets at profits (Sobel 2000).

Stock markets function as a means for controlling management performance. In other words, share prices reflect the decisions and capabilities of the management. Takeovers, hostile or friendly, can be viewed as a market correction mechanism. If the management of a company does not manage its assets efficiently to generate maximum value for its shareholders, then the unhappy shareholders sell their shares in the company and look for better options. The resulting low demand for the company's shares therefore makes the company a relatively cheap acquisition, thus, making it a good target. The rationale for such acquisitions is that the incumbent management is incapable of generating good value from the assets in place. The acquirer considers itself to be in a better position to generate and deliver higher value with the same said assets, either by bringing in a new and efficient management or simply restructuring the business or even breaking it up and selling it off in pieces. The acquisition is then made and very often the incumbent management is replaced with a new one. The aim, once again, is to generate higher value from the assets in place.

In countries, such as the UK and USA, where the percentage of the shareholding is external, there is a higher level of takeover activity.

Countries like Germany and Austria, where the internal shareholding is higher, experience relatively less takeover activity.

Examples of Hostile Takeovers

- Time (US), Warner (US), and Paramount (US) – Time was in the process of merging with Warner when Paramount made a hostile bid. The shareholders of Time were in favor of Time-Paramount merger, but the courts ruled in favor of the Time Management which argued that the Time-Warner merger was in the long-term interest of the company (Saporito 1989).
- Cadbury (UK) and Kraft (US) – Kraft made an offer for Cadbury which was rejected by the Cadbury board. Since Cadbury is almost an institution in the UK, the UK Government also got involved in this hostile cross-border takeover. Kraft made a new offer and eventually Cadbury gave in to an offer of just over \$19 billion (Moeller 2012).
- Sanofi-Aventis (France) and Genzyme (US) – Genzyme had research and products in pipeline that Sanofi-Aventis wanted. Genzyme had rejected their (friendly) offer twice and then the bidding turned hostile. Sanofi-Aventis approached Genzyme's shareholders directly. Eventually Genzyme was taken over by the French company in a deal valued at \$20.1 billion.
- Continental (German)-Schaeffler (German) – is often mentioned as one of the fiercest fought boardroom battles and cost the CEO of Continental, Mr. Manfred Wennemer, his job. Continental had rejected Schaeffler's offers previously. Schaeffler eventually got Continental for around €12 billion in 2008 (The New York Times 2008).

The pertinent issue with hostile takeover is, why is there this hostility? It usually is the fear of losing control or job, or it could be a dramatic change in company philosophy, or it could be the threat of discontinuation of the traditional business model. Given, some such reasons, most companies that

suddenly face unwanted takeover attempts need time to regroup strategize.

Some Classic Defense Mechanisms

There are many defense tactics against a hostile takeover available to the target company. One often hears the term “shark repellent” used as a synonym for takeover defense mechanisms. They, on their own, all have rather entertaining names and the classic ones are the following:

- *White Knight or White Squire* – where the target is bought (taken over) by a friendly company or investor rather than the black knight (the unfriendly bidder). The friendly company usually agrees to retain the incumbent management and most often the acquisition itself is on much more favorable terms. For example, Merck made a hostile bid for Schering and Bayer came to rescue as white knight in 2006 (The Pharma Letter 2006).
- *Poison Pills* – is a collective name for defense strategies, like Flip in, Flip out, Preferred stock plans, etc. The aim of the poison pill is to make the target less attractive to the bidder. This could be achieved, for instance, by making the deal expensive for the bidder. For example, Netflix put in place a “Flip In” in response to the investor Carl Icahn Buying 10% of Netflix’s stock in 2012 (BBC News 2012).
- *Crown Jewels* – usually the last resort, this defense mechanism is the selling off of the most valuable asset the target has to make it unattractive to the bidder. These crown jewels could be both tangible – like a successfully beta tested drug, or intangible – like patents. For example, ABN AMRO tried to sell its crown jewel – the LaSalle Bank Corporation to Bank of America to make itself less attractive to the RBS consortium who made a hostile bid for ABN AMRO. ABN AMRO at the

time was negotiating an acquisition with Barclays who had offered to buy ABN in 2007 (Sterling 2007).

- *Golden Parachute* – originally, are substantial compensations or benefits given to certain key people in the organization in the event they are removed from the organization as a result of a takeover or M&A activity. This usually takes the form of stock options, severance pays, bonuses, etc. Golden parachutes are put in place to once again make the target relatively expensive, since these contracts have to be honored. It is also a way to provide a relatively easier landing after being terminated from work for the personnel. For example, Meg Whitman, when she was the CEO of Hewlett-Packard, contractually stood to get about \$91 million in case of change of control at the company and \$51 million in case she was fired (Bort 2015).
- *Pac-Man* – here the potential target turns around and makes a counteroffer to buy the potential acquirer. This is usually done to intimidate the acquirer. The target may use all means possible to conduct a Pac-Man defense including raising debt, using its own cash, etc. For example, at first, Porsche for some years attempted unsuccessfully to buy Volkswagen. However, in 2012, Volkswagen bought Porsche completely (Topman 2012).

It is important to note that the defense mechanisms most often buy time for the target to regroup and decide upon further strategy. Defense strategies are not fool proof, in that they do not guarantee that a hostile takeover attempt will not happen. The defense strategies however, do allow the target to consider its options. For instance, in 2011, Clorox, the maker of cleaning products rejected an offer made by investor Carl Icahn stating that it undervalued the company. Clorox responded by implementing the defense strategy – Poison Pill to fend off further attempts and to secure better valuation in the market for control (De La Merced 2011).

CSR and Hostile Takeovers

A company should be able to protect itself from unwanted takeover attempts. This is because it allows the management to focus on the business

Hostile Takeover, Table 1 Pros and cons of hostile takeover

Target	Acquirer
Pros	
• The target company’s management manages the assets more efficiently to avoid being taken over in the first place	• Can extract efficiently higher value from assets in place
• In case of a takeover, the target company’s assets can be used more efficiently to deliver added value	• Can acquire assets relatively cheaply
• By having requisite defense mechanisms in place, the target can achieve better valuations	• Can add to existing product market or other aspects of currently business
• Shareholders of the target most often win in a hostile takeover	
Cons	
• Incumbent management is very likely replaced	• Hostile takeovers can be long drawn, and hard fought
• Business might be broken up and sold piecemeal	• In the presence of defense mechanisms, takeovers can quickly become expensive
• Business ethos/model might very likely change	• Key personnel may leave the target organization post takeover making it relatively unattractive
• Job losses across the board are likely	• Expected or planned synergies may prove to be elusive
• Company management may resort to unethical behavior to prevent takeover	• Hostile takeovers may be afflicted by the winners curse often reflected in falling share prices of the acquirer when the hostile takeover is announced
• Acquirers can create undue pressure on the target management to sell	• Could lead to a debt overhang for the acquirer due to the acquisition

and generate value for the shareholders without worrying about being taken over. Another added advantage of having defense mechanisms in place is that the target company can negotiate a higher price for their assets.

However, having too many defense mechanisms in place is considered to be unhealthy for the long-term prospects of the company. The entrenchment hypothesis posits that anti-takeover/defense mechanisms could in the long-run cause management entrenchment. In other words, if the management is not afraid of being taken over, given that they have requisite defense mechanisms in place, then they are quite likely to feel secure, in that they won’t lose their jobs in the event of takeover. The threat of takeover, the hypothesis implies, makes the management perform well in the long-term interest of the company.

If the target management hostility towards the acquisition stems from the fear of job losses or dilution of power, then it is considered unethical. The overriding purpose of any organization is to maximize shareholder value, and if a takeover achieves this, then it should happen. If the target management places its self-interest before the long-term interest of the company and thereby its share/stakeholders, then it is unethical.

The CSR of a company should aim to have in place a fair, transparent, and accountable corporate governance so as to enable objective decision making in the event of hostile takeovers.

Summary

The table below summarizes the pros and cons of hostile takeover for the target company and the acquirer (Table 1).

HR and Corporate Social Responsibility

Definition

The adoption of ethical behaviors during the relationship with the human resources (HR) represents one of the main concepts of the corporate social responsibility (CSR) paradigm. The comprehension of the relationship HR-CSR required a multi-dimensional analysis due to the high degree of complexity that characterizes the dynamics between employees and firms. Specifically, the social dimension of CSR includes all the issues and concerns that revolve around the sustainable work systems and the sustainable human resource management. In these terms, the International Labour Organization (ILO) has been working on raising awareness on the social dimension of sustainability in international law. Its efforts have been recognized by the United Nations in the Agenda 2030. In particular, the SDG 8 “decent work and economic growth” promotes better working conditions and sustainable growth (Di Vaio et al. 2020).

The first perspective of analysis is represented by the direct impacts of the employees' behaviors on the outcomes of the enterprises. In fact, the adoption of unethical behaviors by the staff members could impact negatively on the overall degree of socially responsible activities implemented by the companies. From another point of view, the quality of the work and the performances of the employees are strongly linked with the level of work engagement felt by workers. In these terms, CSR social actions need to be perceptible by the employees (Farid et al. 2019).

The second contribution is represented by the impacts of the firms' strategies on employees' well-being. In fact, the companies could influence the behaviors of the employees through the definition of unethical strategies. On the contrary, the new idea of CSR of "being sustainable by codeveloping with society" requires the participation of the employees for the pursuit of the established goals. Thus, employees need to be a relevant element of the companies that are aiming to achieve sustainable business processes (Chen and Hung-Baesecke 2014). Furthermore, the overall degree of HR's well-being represents part of several indexes that evaluate the overall degree of adherence to the CSR paradigms by the business enterprises.

The HR and the CSR: A Multidimensional Relationship

The concept of sustainable development has been characterized by several evolutions over the years. These evolutions have been favored by the increasing attention paid by academics and policy makers to the sustainable development themes. Specifically, contrarily to the past, the concept of sustainable development is currently characterized by the inclusion of nonenvironmental themes such as the eradication of poverty, the provision of health services for communities, and human rights (Sachs 2012). Furthermore, the policy makers have developed the concept of Triple Bottom Line (TBL) that consists of environmental, social, and economics themes (Sneddon et al. 2006). The definition of the TBL social dimension has been at the center of the debate among CSR scholars. Specifically, it is considered as the measurement and assessment of the organization's impact on the social system in which it operates at local, national, and global level (Elkington 1998).

The social themes are strongly related to the activities of the companies. In fact, firms impact on social themes both through their internal relationships and through their interaction with the external entities. In particular, these processes are interested by the direct involvement of the HR that represents the "human capital" of

the enterprises. In this sense, it is obvious that the adoption of socially responsible behaviors could not be related to the existence of a direct involvement of the employees within the processes. However, the direct involvement of the employees within the processes could be interested by several criticisms caused by the possible existence of conflicts or barriers. Also, it has emerged how the CSR guidelines that have been proposed in the last years do not offer practical contributions in supporting the companies to reach the social sustainability, but provide only assessment tools (Miller et al. 2007). A large number of academics have highlighted that the contributions of the HR to the CSR are several (Voegtlin and Greenwood 2016). In fact, the dynamics role covered by them within the processes required a separate analysis that distinguishes between the socially responsible practices adopted to increase the well-being of the HR and the socially responsible practices directly promoted by the employees (Morioka et al. 2017).

The well-being of the HR has been widely analyzed by academics. The relevance of the topics is related to the increasing attention paid by entrepreneurs to the well-being of the HR. Specifically, several studies have started to empirically test the existence of positive externalities related to the adoption of practices inspired by the exigence to increase the overall degree of HR satisfaction about their jobs. In this sense, some authors have started to discuss about the existence of "humanist" enterprises that operate through business models inspired by a high degree of attention to the HR needs (Del Baldo 2020). Furthermore, other studies have analyzed the systemic impacts of the adoption of socially responsible behaviors on employees. Specifically, these studies have suggested that the development of strategies inspired by the exigence to support the HR during their activities could generate positive externalities on the entire communities (Simone et al. 2019). In addition, according to Hutchins and Sutherland (2008), the realization of sustainable social practices in HR management should involve not only the single company sphere, but also the supply chain. This integrated

approach can be carried out through a strategic selection of the suppliers. Furthermore, prior studies have highlighted that the voluntary adoption of socially responsible practices by the HR could favor the achievement of a highest degree of legitimacy by the business enterprises. In particular, academics have underlined the strategic role covered by the HR within the processes related to the achievement of a social license to operate (SLO) in foreign countries. In fact, an increasing number of MNEs have started to hire local HR in order to adequate their practices to the exigence of the local communities (Forstenlechner and Mellahi 2011).

Summary

The HR are a central part of companies. The development of the human capital represents one of the main strategies to favor the adoption of socially responsible practices. In fact, the two-way relationship that characterizes the connection HR-CSR required the provision of adequate strategies in order to favor the transition to more socially responsible paradigms. Although the literature have highlighted the existence of positive impacts generated by the involvement of the HR, nowadays only a few number of enterprises have started to develop new stakeholder engagement strategies in order to favor dialogue with employees. According to this evidence, academics could favor the development of these practices through the analysis of case studies.

Synonyms

Human Resource Management model; Organizational model for development

Definition

The HRM model envisaged for sustainable development is able to be suitable for achieving results, because it is based on the involvement of excellent professional, it is productive and non-chaotic, motivated, and managed in a peculiar but efficient way, without losing ethical feelings, social commitment, and the cultural choice that remain at the base of the organizational system dedicated to the construction of the human development of a country. For these reasons, we recover the operating model of the solar system. This model well represents the organizational system of the Human Resource Management for development.

The solar system is the planetary system made up of a variety of celestial bodies kept in orbit by the gravity of the Sun. The Sun is the SDS: with its energy, that is, producing human and economic forces, it allows the survival and growth of the system.

Through an increasingly transformational leadership (its gravitational force), it keeps all the planets that follow pre-established orbits around it.

Like the solar wind that propagates creating the atmosphere, so governance generates the organizational culture (adhocracy) that propagates in the organization and permeates the whole environment in which the process of development moves.

Thus, governance, through its leadership style, regulates the functioning (orbits) of strategic and operational plans (planets).

The major risk that this system presents in the model is: “if the sun dies, the solar system dies.”

Introduction

The new theories on sustainable development and ecological economics provide a more complete view of the elements that make up sustainability. In fact, more and more importance is given to the human variable, understood both as the work and as the capital that is created by human beings.

A fundamental component of human development is equity. Every person has the right to live a fulfilling life, in accordance with her values and aspirations. Inequality reduces the speed of human development, and in some cases it can even prevent it at all.

Literature defines organizations in various ways. From Coase in 1937 to Armstrong and Stephens in 2008 (Armstrong and Stephens, 2008), the definitions of the companies followed one another, keeping only one constant element: the shared work.

The organization, in our opinion, consists of “people working together in a collaborative way.”

Key Issue

The sustainable development of a territory requires a double level of action: a top-down action by national and local governments and a bottom-up action by the nongovernmental actors present on the territory. It also requires a division into three strategic phases. It is therefore necessary to imagine a complex management of human resources to achieve the development objective.

The organizational structure destined for the development process is a complex structure, because, especially in the start-up phase, different actors participate.

In our opinion, the most effective structure for a flexible organization that has to develop multiple and contemporary projects linked just by

general services is that of a project first and then a matrix, with a first functional level of corporate. The evolving organization, coming from a hierarchical system, must initially be based on clan culture (with high motivation and trust), but then must strive towards an adhocratic organizational culture, that is, a division into small groups supported by professional staff bodies. This structure is necessary above all for a dimensional development.

To avoid that the structure tends to organizational chaos, it is essential to contain the ample flexibility necessary to work with the transformational leadership style, which must be integrated with a transactional style, to increase the motivation of the human resources employed.

The correct model for a long-term development program should be linked to a matrix structure. It should also be permeated by an adhocratic organizational culture and be conducted with a trans-transformation/transactional hybrid leadership style.

The possibility of linking to the imagined model a system of ethical, economic, cultural, and social rewards becomes necessary to motivate existing resources and to reduce the emigration of valid professional skills towards cities and other sectors.

In this way, the HRM model envisaged for sustainable development is able to be suitable for achieving results, because it is based on the involvement of excellent professional, it is productive and nonchaotic, motivated, and managed in a peculiar but efficient way, without losing ethical feelings, social commitment, and the cultural choice that remain at the base of the organizational system dedicated to the construction of the human development of a country.

The start-up phase of development is based on a strong commitment to organizational planning and monitoring. The goal is to develop the best organizational system capable of achieving results in the short term, through the involvement of external, international, and local human resources.

In all countries (both developed and under-development and in transformation), it is necessary to link the commitment to growth to a system

of ethical, economic, social, and cultural values, both local and international.

The organizational model of the hang-on phase derives directly from the HRM of the previous phase. There are some factors that differentiate it slightly: the peculiarities that link it to the country, the need to reconcile a model that provides for the stable coexistence of a top-down and a bottom-up system, as well as the recent supremacy of the Sustainable Development State.

Therefore, at this stage, it is necessary to identify a model that is not already found in existing theoretical models in business economics. In fact, the peculiarities on which it is based and which represent the strong point of the functioning of the system do not find a precise correspondence in a single theorized system.

For this reason, we recover the operating model of the solar system, already used for the NGOs. This model well represents the organizational system of the Human Resource Management for development (Fig. 1) (Sciarelli, 2015).

The solar system is the planetary system made up of a variety of celestial bodies kept in orbit by the gravity of the Sun. The Sun is the SDS: With its energy, that is, producing human and economic forces, it allows the survival and growth of the system.

Through an increasingly transformational leadership (its gravitational force), it keeps all the planets that follow pre-established orbits around it.

Like the solar wind that propagates creating the atmosphere, so governance generates the organizational culture (adhocracy) that propagates in the organization and permeates the whole environment in which the process of development moves.

Thus governance, through its leadership style, regulates the functioning (orbits) of strategic and operational plans (planets).

Around the planes, like the satellites of the planets, there are NGOs (Hasmath and Hsu, 2015), foundations, companies, or NGAs (Newman et al., 2018; Satar, 2018). Instead, around governance, like comets, are intergovernmental agencies and the international community. While the orbits of the planets (i.e., the operation of the planes) are regular and regulated, those of smaller

HRM of Sustainable Development Phases, Fig. 1 HRM – Solar System (Sciarelli and Rinaldi 2017)

bodies, such as satellites and comets (non-governmental actors and the international community), are less stable. The evaluation of their contribution, for this reason, presents significant risks.

Every single plane is, therefore, like an independent planet, although regulated by the general laws that permeate the solar system. The solar system includes a different working group and external professionals, who, like the planetary rings that are composed of different materials, surround it and support it.

The major risk that this system presents in the model (i.e., “if the sun dies, the solar system dies”) is slightly mitigated in the organizational model of development. In the hang on phase, in fact, the fall of the government and therefore the replacement of the SDS do not involve the “death” of the development system, even if it certainly brings about its change. This is however a critical aspect of the system that must still find a solution (Sciarelli and Rinaldi, 2018).

The HRM model envisaged for sustainable development is able to be competitive with the

outside, because it possesses excellent professionalism, it is productive and not chaotic, motivated, and managed in a peculiar yet efficient way, without losing ethical feelings, social commitment, and the cultural choice that remains at the base of the organizational system.

In this phase, the great task of the scientific community, as evolved planetary rings, is to provide a professional technical support for the organizational functions of planning and management of human resources and not taking time away from development but providing the right skills and educating local resources.

Countries that are in a self-development phase can maintain HRM based on the solar system model. The leadership moves on a more transactional style, the organizational culture remains linked to a managed adhocratic system, the structure confirms a distinct matrix structure between the functions of corporate and the action plans. The difference with the previous phase is only in the composition of human resources that are mainly national, regional, or local.

The HRM of the countries that are in the welfare state, on the other hand, is completely different. In fact, it typically consists of a centralized, functional, traditional organizational system. In this case, the organizational culture is linked to the hierarchy with a centralized control and a very high use of the bureaucracy, and the leadership style is transactional or even dictatorial.

Summary

Human resources are the necessary basis for the development of nations. The capital and natural resources are passive factors of production. Humans, on the other hand, are the active agents who accumulate capital, exploit natural resources, build social, economic, and political organizations, and lead forward national development.

Therefore, the human resource is considered as an important “energy” on which to structure development and above all its sustainability.

Therefore, an important step to be taken for the sustainable development of an area and its globalization must to be level the skills of human resources.

An organization, in our opinion, consists of “people working cooperatively together.”

Human assets management; Human potential management; Strategic human resources management

Definition

The human capital management (HCM) approach enables organizations to analyze, measure, and evaluate how their internal policies and practices create value (Accounting for People Task Forces 2003; Baron and Armstrong 2008). Organizations review their strategic goals and then develop measures to evaluate their performance in achieving these goals. As HCM is concerned with the added value people provide for organizations, it is perceived as a bridging concept that describes the link between HR practices and business performance, creating the basis for a competitive advantage.

Human capital (HC), together with social and organizational capital, builds intellectual capital. HC refers to the specific knowledge, skills, and ability to develop and innovate processed by people in an organization. While acknowledging the importance of people to the organization, HCM stresses the need for managing and evaluating information about people as organizational assets to determine their input in achieving the organization's strategic goals. The value of HC depends upon its potential to contribute to the competitive advantage or core competencies of the firm (Baron and Armstrong 2008).

The Micro-Foundational Level of Human Capital

The definition of HC has evolved over time. The concept of human capital derives from the economic literature, where it was defined as “the knowledge, information, ideas, skills, and health of individuals” (Becker 1964, 2002, p. 1). The Organisation for Economic Co-operation and Development (OECD) (2001) defines HC as the knowledge, skills, competencies, and attributes embodied in individuals that facilitate the creation of personal, social, and economic well-being. The World Bank defines HC as the productive capacity embodied in individuals, with special focus on its contribution to economic production (World Bank 2006). According to this concept, expenditures on personal development (schooling, trainings, and medical care) raise earnings by improving the health or behavior and habits of employees. Economists, therefore, regard these kinds of expenditures as investments in human capital. HC is a specific form of assets, apart from financial or physical capital, which yield income over long periods of time. It is unique in the sense that people cannot be separated from their knowledge, skills, health, or values the way they can be separated from their financial and physical assets (Becker 2008).

Individuals who invest in their education increase their skills and knowledge, are more productive than those who are less well-trained, and earn more as a result of this investment. Thus, human capital theory proposes that employees possess a certain knowledge and skill set gained via education and which can be “rented out” to employers (Ehrenberg and Smith 2018), thus generating value for the organization. Following this concept, costs associated with remuneration, training and development, and career progression should be redefined (Baron and Armstrong 2008; CIPD 2017; Scarbrough and Elias 2002).

Scholars note, however, that treating people as assets is a questionable practice. Employees cannot be treated as passive assets to be bought, sold, and replaced. They are workers who possess

control over these assets – their knowledge and skills – and the extent to which they decide to engage these assets to reach organizational goals depends on them (Davenport 1999).

At the individual level, the core aspects that help develop HC consist of employee training and creating opportunities for learning and career management. The majority of studies have found that HC investments in training generally improve outcomes, such as employee productivity, job performance, rate of turnover, job satisfaction, attitudes, empowerment, teamwork, and commitment. The literature shows mixed results, however, regarding investments in general skills (graduate degree). Some studies have found that these investments can lead to increased mobility and employees are more likely to leave the organization, while other studies stress that these investments are perceived as positive by employees and have no effect on turnover (CIPD 2017).

Human Capital at the Organizational Level

HC is not owned by the organization but is secured through the employment relationship. Human capital can be, therefore, explored at two levels: individual and organizational. At the individual level, HC refers to the characteristics possessed by an individual; at the organizational/unit level, HC refers to the aggregated accumulation of individual HC that creates value for the organization (Wright and McMahan 2011). The capital that is brought by people to the organization is developed by experience and training and leads to the organization, gaining a competitive advantage.

At the organizational level, the literature discusses HC in the context of a resource-based view [(RBV), capability and dynamic capability (DC), perspectives of the firm] and a knowledge-based view (KBV). According to RBV, the organization possesses a unique bundle of valuable tangible or intangible resources, capabilities, and competencies, whereas the combination of these helps to create a sustainable competitive advantage (Barney 1991).

Many firms operate in dynamic and turbulent environments, so they need to be able to transform their constituent resource base, knowledge, and capabilities to remain aligned with external and internal circumstances (Danneels 2002). DC theory proposes an extension of RBV that shows how investment in HC can facilitate employee- and firm-level capabilities through which organizations can gain and maintain a competitive advantage over time in changing environments (Rothaermel and Hess 2007). In turn, KBV treats knowledge as the most important resource of the firm. Organizations able to manage and exploit asymmetries in explicit and tacit knowledge can gain a sustainable competitive advantage (Grant 1996). KBV stresses how the ability to value, assimilate, and apply new knowledge (e.g., absorptive capacity) allows organizations to adapt and respond to changing customer demands (Cohen and Levinthal 1990).

Human Capital: Multilevel Framework

Most definitions of HC focus on the individual level of analysis and stress the knowledge, skills, abilities, and other characteristics of individuals (KSAOs). The extensive number of studies shows, however, growing interest in the organizational outcomes of HC.

In response, a unified approach among individual and organizational perspectives of HC has been proposed. Ployhart et al. (2014) propose distinguishing features between HC resources and strategic HC resources, both of which relate to organizational-level outcomes. The authors define human capital resources “as individual or unit-level (collective) capacities based on individual KSAOs that are accessible for unit-relevant purposes, that is, best practices” (Ployhart et al. 2014, p. 381). At the individual level, HC resources represent a specific KSAO (e.g., an employee can handle specific procedures, can communicate with customers in foreign languages). At the organizational level, HC resources relate the impact of workforce engagement on organizational outcomes, such as customer satisfaction, productivity, employee turnover, or accidents (CIPD 2017).

More recent multilevel HC literature discusses the mutual relationship between the impact of individual level HC and organizational-level performance, including the reverse direction of the relationship, e.g., how the learning climate will enhance employee engagement and extra-role behaviors (Eldor and Harpaz 2016).

Human Capital Management Approach

The literature provides a range of definitions of human capital management. The Accounting for People Task Force defines HCM as an approach to personnel management that treats it as a high-level strategic issue and seeks systematically to analyze, measure, and evaluate how personnel policies and practices create value. Defining HCM as an approach that enables organizations to analyze, measure, and evaluate how their internal policies and practices create value reflects the need for managing and evaluating information about organizational assets and their input in achieving strategic goals (Accounting for People Task Forces 2003, p. 22). Baron and Armstrong (2008) state that HCM provides the basis for strategic HRM through measurement and analysis leading to evaluation, diagnosis, and action. In turn, Kearns stresses that HCM is a holistic, organization-wide, and system-based approach that deals with the development of human potential expressed as organizational value (Kearns 2007). The concept of HCM stresses two core aspects: (1) the current value of HC can be measured in the organization and (2) the future value of HC can be enhanced through investment. Therefore, strategic HR focuses on the practices that can impact HC and explore the mediating mechanisms through which HR practices may drive organizational performance (Wright and McMahan 2011).

Measurement of Human Capital

The basic question for HC refers to the way it is accumulated and becomes obsolete. The economics literature provides three main approaches that

derive a measure of the stock of human capital from information on its various components. The stock of human capital can be measured according to (Task Force on Measuring Human Capital 2016):

1. The cost-based approach, where HC is calculated as being the depreciated value of the stream of past investments, including investments coming from the individual, the family, employers, and governments.
2. The lifetime income-based approach, where HC is measured by summing up the discounted values of all future income streams that all individuals in the population expect to earn throughout their lifetime.
3. The indicator-based approach estimates HC based on educational output indicators.

The need for measuring the value of HC and exploring how it should be managed to gain a sustainable, competitive advantage remains the core aspect of human capital management. According to the CIPD, measurement of the impact of HC on organizational goals (such as customer satisfaction or innovation and service delivery) is difficult, as the outcomes are also influenced by other contextual factors. They state that “Given the complexity of organizations and the various approaches to managing human capital, measurement can be challenging. The context of the organization is also a fundamental aspect of human capital measurement: the emphasis for measurement is no longer on absolute measures of human capital, but instead context-specific information to enable informed decision-making” (CIPD 2019). CIPD groups HC data according to the different aspects of HR (CIPD 2019):

- Workforce composition: demographics data including age, gender, and ethnicity.
- Recruitment and retention: number of resignations/vacancies/applications, length of service.
- Skills, qualifications, and competencies: levels of expenditure on training, types of training provided, length of time to reach competence levels, data on training needs.

- Performance management: performance management results, productivity and profitability data, targets set and met, levels of customer satisfaction, customer loyalty.
- Employee relations and voice: findings from employee attitude surveys.
- Pay and benefits: overall wage costs, distribution of individual performance-related pay awards, level of total rewards package.
- Regulatory compliance includes data on the compliance of employees with established standards and guidelines in particular disciplines.
- Organizational development and design includes data on skills mix, and talent pipelines.

In turn, Wright and McMahan (2011) distinguish three types of HC measures: subjective, proxies, and direct assessment.

Subjective measures assess the perception of HC among managers and enable a deeper understanding of HC in organizations. Frequently, these measures employ Likert scales or anecdotal evidence to gain information about particular organizations. One example is as follows:

- (a) “Our employees have a suitable education for accomplishing their job successfully.”
 - (b) “Our employees are well-trained to accomplish their jobs successfully.”
 - (c) “Our employees have suitable work experience for accomplishing their jobs successfully.”
 - (d) “Our employees are well-skilled professionally to accomplish their jobs successfully.”
- Carmeli and Schaubroeck (2005)

Proxies used for estimating HC (i.e., stand in for other quantities that cannot be directly measured) are more prevalent in the economic and macro-organizational areas. The literature, however, provides examples of using proxies for providing insight into the role of human capital in organizational performance (Wright and McMahan 2011). For example, Hitt et al. (2001) assess HC in law firms using proxies as:

“quality of law school attended by partners,” “experience as partners in the current law firm,” and “total partner experience in the legal field.”

Direct assessment approaches to measuring HC come from the field of psychology and are linked to individual traits as important aspects of HC (e.g., personality traits, emotional stability, extraversion, educational success, level of education achieved, years of experience). When using direct measures, it is important to note that the number of years spent in education does not assess the quality of the education.

Sustainable Approach Towards Human Capital Management

Human capital management enables organizations to identify, analyze, and manage the interdependencies between HC and business performance. The changing business environment also forces organizations to adapt to new circumstances and respond to the expectations of external and internal stakeholders.

Certain concepts and approaches may be perceived and developed by using the perspective of corporate sustainability and corporate social responsibility (CSR). In the case of HC, they may be seen in the language used to express the concept by OECD. In 1996, OECD defined HC as “the knowledge that individuals acquire during their life and use to produce goods, services or ideas in market or non-market circumstances” (OECD 1996); in 2001 the definition was changed to: “the knowledge, skills, competencies and attributes embodied in individuals that facilitate the creation of personal, social and economic well-being” (OECD 2001, p. 18). The purpose of HC development was shifted from the business performance to “personal, social, and economic well-being.” This also encourages scholars and organizations to think in broader terms about the way HC is maintained and developed within the organization.

An example of an aligned model of HCM that refers to the perspective of corporate

sustainability and CSR was proposed by van Marrewijk and Timmers (2003). The authors suggested an analysis of the relationship between the organization and the employee, not through the perspective of an economic contract but through a complex work situation in which employees need to find alignment of values, goals, and responsibilities of individuals and the collective. The authors propose that this alignment be evidenced in three domains: (1) personal and company values (corporate identity and values); (2) human operations – when operational and supporting processes take place in a context of dialogue and alignment, the degree of empowerment and individual performance indicators are in mutual agreement and align the personal characteristics of HC with the collective needs of the organization; and (3) human development, where the tempo of development inside and outside the organization should be aligned, along with the direction and extent of competence development with respect to individual employees (Van Marrewijk and Timmers 2003). The researchers concluded that this kind of alignment can both increase organizational outcomes and help organizations overcome challenges.

Summary

The concept of HCM is concerned with the added value people provide for organizations and provides linkage between HR practices and business performance, creating a basis for a competitive advantage. Therefore, organizations strive for strategic goals and set measures in order to evaluate their performance. HC can be considered at both individual and organizational levels. Recent studies describe HC also as a multilevel construct and indicate both personal and organizational outcomes. As HC is perceived as one of the most important assets enabling innovation and adaptation to changing circumstances, organizations invest in HC maintenance and development. Thus, workers, not companies, possess control over these assets. It is necessary, therefore, for

organizations to seek alignment of individual and organizational goals and interests.

Human Development Index (HDI)

Sefer Aydoğan

Military and Social Science Department, Air Force Academy/National Defense University, İstanbul, Turkey

Synonyms

HDI; HIHD; Social welfare measurement

Definition

HDI is an average measure of basic human capacities as well as a brief measure of human development by means of social and economic development. HDI measures a country's average achievements in four areas. These are years of schooling, expected years of schooling, life expectancy at birth, and gross national income per capita. This practical instrument monitors and compares the development of countries over time (Investopedia 2019).

Introduction

Economists have long considered the Gross National Product (GNP) per capita as a core variable to measure and explain the economic development of a country. GNP per capita fails to capture developmental progress and dimensions of human welfare – in particular the living standard, health, schooling, life expectancy, etc. An alternative measure has been provided by the United Nations Development Programme (UNDP) in its *Human Development Report* (HDR) based on the “Human Development Index” (HDI). HDR defines human development as “a process of enlarging people's choices” (Kelley 1991).

The HDI is an index developed by the United Nations (UN) to calculate and compare nations'

economic development level. The Human Development Index (HDI) is a composite statistical methodology of key variables of human well-being. Since the last few decades, the United Nations Development Programme (UNDP) performs both standard HDI methodology and the long-run Historical Index of Human Development (HHID) which was developed by Leandro Prados de la Escosura. Although the characteristics of the two indexes are almost the same, the difference arises in how the index variables are rooted. Explicitly, HHID segregates from HDI in calculation of adult literacy, educational enrolment rates and gross domestic product (GDP) (Roser 2019).

Objectives of the HDI

The HDI is also a crucial tool to evaluate a nations' potential economic development level besides considering the economic growth rate. According to the *Human Development Report*, human needs must be centered on economic development (Anand and Sen 1994). One goal of the HDI is to explain policies for sustainable development level. Thus, the HDI can also help government authorities and policymaker, asking why two countries have the same GNP per capita but different index values (UN Development Programme 2019). However, the HDI has been discussed by the policymakers for not showing meaningful information on the standard of living. Moreover, definitions, measurement, and the inclusion of the components are also a problem which varies from country to country. Thus, HDI values help policymakers and institutions to develop and indicate their development plans.

History of HDI

The HDI is rooted in Amartya Sen's "capabilities" hypothesis to analyzing well-being, which indicates the results (such as living standard, access to health, education, and goods) over means (such as

GNP per capita) (Sen 1985). The "capabilities" approach to human well-being refer to the ability of a human being, rather than on what they already have (Stanton 2007). Economic institutions and policymakers have attempted to extend the index of human well-being that shed light on both ends and means of development. In 1966, the United Nations Research Institute for Social Development (UNRISD) published a "level of living index" as one of the earliest indexes that had categories for physical needs, cultural needs, and higher needs (income) (Stanton 2007). The United Nations Development Programme (UNDP) launched the first annual *Human Development Report* (HDR) in 1990 (Neumayer 2001). HDR indicates the concept of "human development" and achievement toward human well-being (Stanton 2007).

How Is the HDI Measured?

The HDI calculation starts with the calculation of a "deprivation index" for each selected indicator of human development (Kelley 1991). The HDI indicates an index which applies to three main variables of human development: life expectancy, level of knowledge, and a reasonable living standard (Roser 2019). Four indicators are used to calculate (Fig. 1):

Life expectancy
Expected schooling years
Average schooling years
GNP per capita

There are two steps to calculate HDI:

First, each of these indicators is normalized to scale between 0 and 1 and determines maximum and minimum levels for each indicator. In detail, life expectancy at birth is equal to 0 when life expectancy is 20 and equal to 1 when life expectancy is 85, as same as for schooling years or expected schooling years. Moreover, GNP per capita is also calculated and normalized between

Human Development Index (HDI), Fig. 1 Human Development Index (HDI) (Source: Komlos and Snowdon 2005)

0 and 1 levels that are given the highest GDP per capita and the lowest GDP per capita level. So, the HDI is quite sensitive to the choice of minimum and maximum values for each human development indicator (Kelley 1991).

Second, aggregating the three-dimensional indices to produce the HDI (UNDP 2019). The Human Development Report Office (HDRO) forecasts the unknown variables by performing econometrics and other quantitative methods (UNDP 2019). The *Human Development Report* based on the HDI results introduced four-country groupings of human development level: low, medium, high, and very high human development (UNDP 2019).

Summary

Human Development Index (HDI) is a practical instrument to calculate and compare nations’ economic development level. The outputs of the index are beneficial for generating strategies and policies to advance the life of the society. The United Nations Development Program (UNDP) set forth some dimensions to measure the development level such as life expectancy, expected schooling years, average schooling years, and gross national product per capita. There is a two-stage calculation method.

Data Sources (UNDP 2019)

- Life expectancy variable: United Nations Department of Economic and Social Affairs (UNDESA)
- Expected years of schooling: United Nations Educational, Scientific and Cultural Organization (UNESCO) Institute for Statistics, ICF Macro Demographic and Health Surveys*
- United Nations Children’s Fund (UNICEF) Multiple Indicator Cluster Surveys and Organization for Economic Co-operation and Development (OECD)
- Mean years of schooling: UNESCO Institute for Statistics, ICF Macro Demographic and Health Surveys, UNICEF Multiple Indicator Cluster Surveys, and OECD
- GNP per capita: World Bank (WB), International Monetary Fund (IMF)
- United Nations and its group of other international institution statistics division

Definition

Human rights represent rights that are universal and inalienable, and are possessed by all people regardless of race, gender, nationality, or any other status. As such, the concept of human rights is a relatively modern concept, but the ideas behind the concept have long been known in philosophy. Although various philosophers mostly agree on the power that human rights carry, as well as on their formal properties, the point of disagreement lies in the source of human rights. There are various attempts to justify human rights, and the most famous are those from religion, legal positivism, sociology, and natural law. Apart from philosophy, the ideas that supported the development of the modern concept of human rights are also hidden in legal documents. This entry offers a description of the history of philosophical ideas as well as legal documents that led to the development of the modern concept of human rights, as well as a critique of them.

Introduction

Human rights are defined as rights that belong to every human being regardless of nationality, gender, race, religion, language, or any other status. Human rights derive from the fact that someone is a human being and as such contains a quality from which moral norms for action arise. Although it is considered that at the same time as humans we have human rights, the formal implementation of human rights in law and declaration is more modern history. On the other hand, the very idea of human rights existed long before any legal implementation of them. The ideas of the principles underlying the idea of human rights, the equality, and universality of the moral law can be found in early philosophical writings.

Justification in Philosophy

Philosophy and the idea of human rights are closely related, if not intertwined. Rather, philosophy is needed to justify the existence and promotion of human rights. Many people take the validity of human rights for granted but philosophers do not like human complacency, so they look for valid reasons for the establishment and implementation of human rights. Human rights derive from moral laws, and moral law deals with what ought to be the case, not with what is or is perceived to be the case. We cannot look for the justification of the moral law in empirics since it deals with norms and not empirically available facts. The justification of the moral law, as well as the human rights that derive from them, should be sought in moral philosophy.

History of Human Rights

Philosophical considerations and arguments about natural law and natural rights are important because they precede and anticipate the concept of human rights. Knowledge of philosophical assumptions enables a better understanding of one's own views on human rights. Without understanding the philosophy that shapes attitudes, the

attitudes themselves will be unclear. Also, knowledge of philosophical considerations offers an understanding of the moral justifications behind human rights, thus becoming faithful to them. This is extremely important in countries that have not legally implemented human rights. After all, knowledge of philosophical considerations enables open communication, rejecting any dogmas.

History of Human Rights in Philosophy

The beginning of the idea of human rights begins with Aristotle, who in the 300 BC argues in favor of the existence of natural law (Aristotle 2004). Natural law represents a system of justice that does not arise from society or culture, but from nature itself, therefore it is common to all people. Natural law is universal and it applies to every human being at every time preceding contingent social and historical conditions. Aristotle believes that certain principles of natural laws are arrived at by practicing reason or virtues without being influenced by prejudices or personal desires. Natural law serves to make a comparison with the artificially created laws of certain societies and to assess their legitimacy. The difference between natural law and legal justice is that natural law does not have to be introduced as formal law to be valid while legal justice by definition has to be introduced into formal law to be valid. The ideas of natural law from Aristotle are taken over and elaborated by the Stoics of the Hellenistic period, and later of the Roman period. The idea itself becomes extremely popular and is mentioned in various works of art, such as Sophocles' *Antigone*, who opposes Creon by burying her brother, referring to the natural law that is above kings. After the Stoics, the idea of natural law flourished in the Middle Ages, where Christian philosophy and theologians took over. The most famous among them is St. Thomas Aquinas who argues in favor of natural law that originates from God who has given human beings immutable and inalienable rights because people are created in His image. St. Thomas Aquinas goes a step further and says that legal laws are not legitimate laws if they contradict natural laws. In a situation of conflict between these two laws St. Aquinas

believes that one should follow the natural law, necessarily violating the legal one (Aquinas 2007). The idea of God as the Creator and Giver of natural law begins to weaken with the disappearance of feudalism, and secular theories of natural law begin to appear as a replacement. The credit for separating natural law from religion goes mostly to Hugo Grotius.

Grotius believed that the natural characteristic of human beings is the social impulse that leads them to live in peace and harmony with others. An action that corresponded to the nature of people as rational beings was good, and an action that undermined that order was bad. For him, natural law was the dictate of right reason (Rommen 1936). Although Grotius removes the idea of God from natural law, these arguments were not strong enough to survive, therefore John Locke, as one of the leaders of the idea of natural law in the Enlightenment, returns God to the center of the theory. Locke believed that every man has natural rights, regardless of whether political institutions recognize this or not. Natural rights derive from natural law, and natural law derives from God – a discerning discernment of God's will gives us a definitive and authoritative moral code. The individual has the duty of self-preservation towards God, and the realization of self-preservation requires the existence of the right to life, liberty and property. Governments are formed exclusively for the promotion and protection of natural rights. Therefore, natural rights also serve as a limit to the authority and jurisdiction of the state. Locke goes further than St. Thomas Aquinas and writes that it is morally justified to take up arms if the state does not systematically and deliberately protect human rights (Locke 2016). In his philosophy, Locke provides a precedent for the establishment of legitimate political authority based on natural rights. Also, he builds the idea of natural rights from natural law, which is closest to what we consider today as the concept of human rights. Considering how the Age of Enlightenment wanted to break the connection between the state and the Church, the current at that time was not completely satisfied with Locke's theory, so someone was needed who would completely

exclude God from natural rights. Arguments for such expulsion were provided by Immanuel Kant, who based his natural rights and necessity for self-preservation on the authority of human reason. For Kant, morality rests in the condition in which my being is obligatory for all human beings; doing the right thing is determined not by acting in accordance with one's own desires or God's desires but by acting in accordance with a maxim that all rational individuals are bound to accept. Kant calls it the categorical imperative: it acts according to that rule which you can wish to become a universal law (Kant 2005). Kant's moral philosophy is extremely abstract, but what he deserves credit for is that he justified human dignity by possessing reason. According to him, every natural right derives from the formal properties of human reason, and not from the will of a superhuman being. With his arguments, Kant popularized the universality of natural rights as well as equality and moral autonomy.

History of Human Rights in Legal Documents

Knowing the course of philosophical thought that preceded today's concept of human rights, but also that is hidden in the concept itself, we have a better understanding of them. Based on this, an overview of the legal documents that enabled the development of human rights will be offered.

The first civilizational legal documents that resemble the concept of modern human rights can be dated to more than 1500 years BC. Although such ancient legal records remind us of today's concept of human rights, they cannot be equated with human rights because such laws were not universal: They were valid only for a certain society. Also, the ruler, resident and slave did not have equal rights in any matter.

The first such legal document is the Ur-Nammu Code written in stone in the ancient language of the Sumerians in the 2000 BC. The code mentions the provisions of respect for the human being such as not to commit murder or kidnapping. Three hundred years after the code, the law of King Hammurabi, who ruled Babylon in the first half of the 1700 BC, was written down. His law was also carved in stone and bears certain hints of ideas of justice and protection. Such a law

prescribed, among other things, that slaves must not be abused, that people must be protected by the law, and that the ruler must be guided by the law, and not arbitrarily rule as he wishes. Furthermore, from 539 BC there is a legal document of Cyrus the Great, the first king of Persia, called the Cylinder of Cyrus. Cyrus Cylinder gave freedom to slaves, brought racial equality, and allowed people to choose the religion they wanted. The provisions of the Cyrus Cylinder are parallel to the first four articles of the UN Universal Declaration of Human Rights, and the text has been translated into all six official languages of the United Nations. After the Cylinder of Cyrus, a major shift towards human rights was created by a document from 1215 called the Magna Carta or Great Charter. The Great Charter was signed by King John of England, and it mentions the right to own private property. In addition, the Great Charter also talks about the protection of individuals from the imposition of excessive taxes.

After the previously mentioned documents comes the Age of Enlightenment, in which the concept of human rights undergoes a revolution with the frequent issuance of legal documents. Thus, in 1628, the Petition of Rights was issued, which the English Parliament sent to King Charles I as a declaration of civil liberties. More than 100 years later, in 1787, the US Constitution was issued, which defined the fundamental rights of citizens, as well as visitors to the state, as well as limitations on the activities of political bodies. In 1791, just 4 years later, as part of the aforementioned constitution, the Charter of Rights was issued, which grants freedom of religion, speech, and action, and prohibits the authoritarian taking of property, life, or freedom of a human being by another human being or political institutions. Also, this Charter allows the right to own weapons as a possible defense in case the government becomes authoritarian and starts to violate these rights. While the American Revolution culminated with the aforementioned Charter, the French revolution culminated with the Declaration of the Rights of Man and Citizen in 1789. The declaration demands that all citizens be provided with property, security, freedom, and the possibility of resistance to possible oppression of these rights.

The Declaration also notes that these rights are limited to allowing others to enjoy those same rights. After the Age of Enlightenment in 1864, the Geneva Convention was held. The theme of the Geneva Convention was the treatment of soldiers and people in war, and it declares the obligation to provide care to wounded and sick people in war, regardless of nationality, race, or other status. Also it states that attacks on Red Cross personnel, i.e., medical and humanitarian aid personnel, are prohibited. The modern concept of human rights was realized in 1948 after the horrors of the Second World War when the United Nations, led by Eleanor Roosevelt, published the Universal Declaration of Human Rights. Roosevelt called the published declaration the international Magna Carta – for all humanity. The declaration consists of 30 articles that emphasize basic political and civil rights such as freedom of thought, expression, religion, and association, but also economic, social, and cultural rights such as the right to education and the right to fair payment. The Declaration refers to negative freedoms such as freedom from torture or slavery and to positive freedoms such as freedom of movement. The declaration does not take the position that certain rights are more important than others, but instead refers to universality, indivisibility, and interdependence. The UN's Universal Declaration of Human Rights was supplemented by later documents. Thus, in 1953, a legal document called the European Convention for the Protection of Human Rights and Freedoms was issued, and in 1966, a document called the International Covenant on Economic, Social and Cultural Rights. American historian Samuel Moyn argues the thesis that the full concept of human rights came to life after those documents – in 1968 (Moyn 2011).

Where Do Human Rights Come From?

In a brief overview of the history of the philosophical idea of the concept of human rights, it is evident how different philosophers justify the concept of human rights in different ways. For some, God is needed to justify the dignity of every human being, while for others, human

reason is sufficient. Although all philosophers agree on the power of human rights as well as their formal properties and objects, the arguments in support of human rights are often different – sometimes even diametrically opposed. The further continuation of the text aims to determine the main theories of the justification of human rights. The central question in justifying them is where they come from, and the main theories are religion, natural law, positivism, and sociological theories.

Religion

In various religions around the world, the concept of human rights is not directly mentioned, but they are imbued with the concepts of higher laws that come from God and are superior to secular laws. In Christianity, in the first book of the Bible, the Book of Genesis, it is mentioned that God created man in his own image, which implies certain truths about man: That he possesses dignity and requires a special relationship with himself in relation to other living beings. Furthermore, the Koran mentions that every human being possesses dignity, while the holy book of the Hindus, the Bhagavad Gita, mentions that he who sees God in every human being truly sees. The religion believes that human rights come from God, that each person is special because God created them, and that these rights are inalienable because they come from an eternal being, therefore no contingent authority can take them away. The problem with the derivation of human rights from a supernatural being is that the question arises as to which rights derive exactly? It is not uncommon for different religious experts of the same religion to differ in their answers to that question. Also, although God created all human beings, it is often found that certain religions have different rights depending on whether it is a woman or a man. Also, in certain religions non-believers and believers of other religions are often treated inhumanely. However, if someone wants to exclude God from the story of human rights, more problems arise than solutions, because the necessary metaphysics of human rights is eliminated and human dignity is difficult to explain in secular terms.

Natural Law

The idea of natural law originates from Aristotle, who himself mentions an unmoved mover in his philosophy, but for him this unmoved mover is not a God but a necessary metaphysical concept. Natural law represents the idea that justice is acting in accordance with human reason. Practicing human reason leads to the identification of human rights. Any action that affirms human beings as rational is good, and any action that nullifies human reason is bad. Arguments in favor of the natural law can be found among religious thinkers, but unlike most of the Enlightenment, they see its cause in God, and not in reason as such. The problem that arises with the natural law theory is that it brings new questions into the discussion such as where do people get reason from? The reason why religious authors accept the natural law theory is that they look to reason as proof that we are made in the image of God. On the other hand, the Enlightenment has a problem in explaining where reason comes from as the backbone of human rights. Also, the theory of natural law has problems with determining concrete rights that would be treated as inalienable. Depending on the understanding of the concept of nature, different theorists of natural law will give different human rights.

Legal Positivism

Legal positivism denies any possibility of acquiring human rights a priori and considers that the source of human rights is the state. If the state has prescribed something by law, it is a right, and if not, then it is not a right. Legal positivism is based on empirical facts and does not deal with the question of what laws should be because it believes that such a question has no place in the theory of law. Given that it is based on empirical facts, it denies any intervention of a supernatural being, but also natural law, thus denying the metaphysical aspects of human rights. The problems arising from legal positivism are multiple. Positivists believe that the law must be followed just because it is the law regardless of whether it is moral or not. They do not distinguish between law and morality because morality is not an empirical construct and therefore should not even be used in

this discussion. It follows from such an attitude that people who lived under some extremely immoral laws, such as some in the Second World War, had to follow them because the state said so. The theory of legal positivism was often invoked by various authorities of despotic regimes. Although the theory contains many shortcomings, it is good in that it emphasizes the importance of the state to recognize that something is a right due to the formation of a legal body that would promote the said right. It is necessary that it does not remain only on recommendations and considerations, but that the rights are also implemented in the legal law.

Sociological Theories

With the development of psychology, anthropology, sociology, and other human sciences, the sociological theory of law also appears. Sociological theory is based on the fact that human rights arise from human interests, therefore by acquiring knowledge about human interests we also acquire knowledge about human rights. Ensuring the essential interests of human beings is the main basis on which human rights can be morally justified. Sociological theory focuses on the identification of social and biological prerequisites that are necessary for a human being to lead a minimally good life. Human rights are justified on the basis of their instrumental value to ensure the necessary conditions for minimum human well-being. The fundamental interests of man would be life, knowledge, play, aesthetics, socialization, religion, and intelligent and reasonable discussion. Each individual must recognize these interests and, as part of that, respect other people's interests because it is in their interest. In sociological theory, respect for human rights stems from self-interest, not from altruism or benevolence. It also follows from such a theory that the goal of legal and political institutions is not to promote the common good but personal interests. The criticism of this approach lies in the fact that people often act altruistically without satisfying their personal interests. Also, this approach is based on the assumption that all individuals are equally

vulnerable to each other, therefore they will respect other people's interests. In reality, what happens often is someone is more vulnerable than the other, therefore they will not respect the interests of the subject in order to satisfy their own interests. After all, people are diverse and interests vary depending on culture, and even when they have the same interests, the ways to satisfy those interests are often not the same.

Criticism

The modern concept of human rights is popular and widely accepted due to the positive atmosphere that the concept itself carries. No, although the concept exudes positive connotations, abuses of it are possible, so there was no lack of criticism of the very concept of human rights. The same criticisms can be divided into criticisms of individual philosophers and group criticisms of individual philosophical schools.

Criticism by Individual Philosophers

Modern criticism questions the universality of human rights. Universality makes human rights too abstract and thereby deprives them of their meaning. Hannah Arendt, a philosopher who survived the Holocaust, recalls how, after the Jews were stripped of their right to citizenship in the Second World War, the only appeal left was to abstract human rights. If someone is not granted citizenship, then that person has no political and legal institutions that would fight for his human rights. With the abolition of the right to citizenship, the Jews turned from an active and realized political subject into an object that is at the mercy or displeasure of others. What makes people bearers of human rights is not the mere fact that they are people, but the fact that they have the possibility and ability to create political societies that are promoters and defenders of human rights. The lesson that the Jews learned in the Second World War was not to focus more on human rights per se, but to form political and legal bodies that would defend their right to citizenship, and that is

why they created the state of Israel after the Second World War. Arendt believes that human rights are smaller and weaker than the rights of civil rights. The holder of human rights is always in an inferior position because he depends on others, while civil rights are created by citizens and are represented by a clear political and legal body. Furthermore, the famous German philosopher Carl Schmitt also criticizes human rights, but from a different position. He believes that any military intervention aimed at restoring human rights is actually at its core an act of power, not an act of principle. Schmitt takes a similar position as certain theologians such as St. Thomas Aquinas, who says that other countries should not interfere in the business of overthrowing a dictator in another country, because one can never know whether the situation will be better or worse. The best modern example of this thought would be the situation with the US intervention in Libya, where many theorize that the overthrow of Gaddafi in the name of human rights left a much worse situation than with him. In addition, Schmitt agrees with Arendt and says that human rights are too abstract. He understands the call for human rights in the American and French revolutions, but also before that, as a call to fight against despotic regimes, but that by no means meant that the era of universal human rights had arrived. The fact that the world does not have a universal government that would have the authority to distribute universal rights and that the world is divided into different states and political societies means that there is no such thing as an individual bearer of human rights. In Schmitt's and Arendt's critique of human rights lies the greatest paradox of human rights: They are created in the circles of illegally recognized political institutions and as such can serve as a source of acts of manifesting unjustified power (Chandler 2017).

Criticism by Philosophical Schools

In addition to individual criticisms of human rights, there are also entire philosophical schools that disagree with the concept of human rights.

Thus, for example, philosophers who support moral relativism do not agree with the concept of human rights. Human rights are based on the idea of moral universalism, and this idea is the opposite of moral relativism. Moral relativism believes that moral principles are not formed a priori but are a product of the society and time in which we live. As evidence for their claim, moral relativists present the fact that there are societies with totally different moral beliefs, sometimes even the opposite. On the contrary, it is often possible to find that there are different moral beliefs in the same society. Moral relativists criticize the current concept of human rights because they believe that Western societies have imposed their values on them by emphasizing civil-political liberties over socio-political rights and in favoring individual rights over group rights. On the other hand, observing that there are different moral concepts in different societies does not justify moral relativism because there are societies that do not respect any human rights. Moral relativists mostly do not defend such societies, but various dictators, to defend their actions, appeal to moral relativism. Also, there are moral norms that are recognized in all societies, such as the prohibition of incest. In addition to moral relativism, there is also an epistemological criticism of human rights, which is based on the fact that there is no rational or metaphysical justification for them, but that they are based on human emotions. According to epistemic criticism, morality resides in the heart, not in the head, therefore no amount of exercise of reason can reveal moral norms. In its desire to remove metaphysics from human rights, epistemic criticism removed reason, depriving man of the greatness he deserves as a creature.

Conclusion

Human rights represent universal and inalienable rights that every human being possesses simply by being human. The realization of human rights in a legal document is an activity of the modern

world, but the very idea of human rights existed in ancient civilizations. Given that the idea of human rights is closely related to moral philosophy because it deals with norms and not empirical facts, most discussions about the idea itself can be found in philosophical writings. Although philosophers mostly agree on the power that human rights carry, they differ on the issue of the origin of human rights, so some claim that they come from God, some from natural laws, and some simply from legal acts of the state. No theory is perfect, but what is important is that everyone recognizes the importance of human rights as such and works to ensure that they are recognized and promoted in the world, thus making the world and the society around us safer and more pleasant to live in.

Summary

Human rights are rights that all people possess regardless of race, gender, nation, or any other attribute, and by definition, they are inalienable. This concept of human rights is a relatively modern concept, but the ideas behind it have developed throughout history, mostly through philosophy. This entry offers an account of the history of the development of the modern concept of human rights, showing at the same time the development of ideas as well as the legal documents that accompanied them.

Definition

Humanistic management and entrepreneurship (HME) is both “a new economic paradigm (Melé 2009) as well as an alternative view of the firm (Fontrodona and Sison 2006; Sison 2007)” (as quoted in Spitzeck 2011). HME provides a normative perspective on how business should be conducted according to ethical, social, and environmental sustainability and a positive empirical research agenda on how businesses are created or reformed accordingly. HME represents a collection of theoretical stances, strategical studies, and empirical enquiries aimed to overcome the idea of the economic discipline as being eminently a science of “value” and propose the idea of it being the science of “values” (Pirson 2014). Indeed, it seeks to explore how nonstrictly related economic variables (such as spirituality, cultural and artistic sensibility, and commitment to justice and democracy) affect economic behavior, entrepreneurship, governance, and business models. This paradigm thus entails the need to bridge technical knowledge, social sciences, and humanities contributions in order to pursue socially oriented goals of the firm, the economic system, and of the economic discipline.

Introduction

In the last two decades humanistic management, together with the reflection on Humane Enterprise, has collected a significant number of studies that focus on reforms keen on more sustainable, socially oriented, and values-based business models, as a way to face “grand challenges” of our time (Waddock 2020; Eisenhardt et al. 2016). Due to its feature of “economy serving life,” HME is presented as a field of study with its own peculiar ability to confront social consequences and impact of economic downturns, such as the one followed to the 2008 Great Recession, rising inequality, climate change (Schlag and Melé 2020), and, recently, Covid-19 pandemic; moreover, its scholars seek to monitor and contribute to the meeting of the UN 2015 SDGs objectives. Although similar insights had circulated before, only recently HME has acquired sufficient scholarly coherence, a significant number of contributions, and has reached so wide an audience to be considered a reliable theoretical framework with a distinctive perspective (Melé 2013). Given its status of a *paradigm in the making*, this perspective is subject to a continuous stream of research aimed to detail and discuss its main features (Pirson et al. 2014) and to provide additional formalization to its framework (Parente 2018).

In the late second half of the twentieth century the term humanistic management has been discussed as a way to conceive management as being linked above all with human motivation (Herzberg 1976; Swart 1973) and as a practice entrenched with a wider understanding of life and society, focusing on motives for action exceeding profit-related goals (Lilienthal 1967; Cunningham and Tichy 1983). Indeed, one of the pillars of the HME paradigm, the idea of the firm as a community-based organization rather than an individual-centered organization, had already been discussed during the 1970s (Drucker 1973). During the 1990s, the idea of focusing on individuals, their values, and their particular desires and talents when doing business began to circulate among scholars and business actors who were concerned with human needs and societal

development within production process (Aktour 1992; French and Bell 1999). The latter suggestion can be conceptually tied to a wider understanding of the issue of dignity in workplace and of the benefits of inclusion and involvement for workers (Barnard 1968; Handy 1999). The circulation (among others) of these perspectives, although not explicitly framed as HME, has paved the way for a more comprehensive theory of the firm as an economic organization built around human needs instead of the other way around, a vision alternative to economicism that has been systematized and summarized by HME recent conceptualization (Melé 2013).

By collecting the abovementioned insights and by adding to them a reform program for business and management with systematic ambitions, in the first decade of the twenty-first century the effort to provide a humanistic management paradigm with its own distinctive features and methodology has reached its peak. More on the point, scholarly efforts in the field have been focused on providing humanistic management with a proactive approach rather than a reactive one (Pirson 2014) focusing on proposal rather than more on critique of previous and competing approaches. Although humanistic management still lacks a unique definition, it compels a set of perspectives bond together by a conceptualization provided as follows: “a management that emphasises the human condition and is oriented to the development of human virtue, in all its forms, to its fullest extent” (Melé 2003: 79).

In order to pursue this vision, HME develops coherent frameworks able to explain motivations and consequences of humanistic oriented business behavior and to provide business models based on the understanding of the economic sphere as being embedded within meaningful horizons that would otherwise escape economic explanation. Therefore, it addresses the impact of concerns for what is “higher” than the profit dimension: such as beliefs in transcendence and religious values, as well as profane ideas of greater good, as part of individuals and communities’ life (Bouckaert and Zsolnai 2012); it addresses concerns for integral ecology (Jakobsen and Zsolnai 2017) and local communities (Del Baldo 2018, 2020), thus for

what is “surrounding” production. In the same manner, it addresses concerns for what is “below” the entrepreneurial and managerial level, by bettering working conditions and preserving dignity in workplace, also linked to participation, cooperation, and workers’ involvement in the goals of the firm (Pirson 2019; Mollner 2011).

Based on evidence that nor the profitability argument alone nor the moral concern taken on its own are able to explain responsible behavior (Spitzeck 2011), HME has developed a theoretical understanding of the variety of values-based motivations and goals that can be pursued, by adopting a multidisciplinary vision. HME engages in the discussion of variables that rest within the area of overlap in between economy and society, by proposing the merging of noneconomic knowledge with the economic discipline (Greenhalgh et al. 2020).

Moreover, as a result of the growing interest in humanistic management both at a theoretical level and as a set of good practices analyzed through empirical evidence, the humanistic management network has been created to provide international and organized support to the development, discussion, and dissemination of this perspective (Spitzeck et al. 2009).

Key Issues

“The challenge of Humanistic Management,” as it has been defined by Melé (Melé 2003, 2013), rests on both the possibilities and the difficulties of the transition from economicism to humanism. Challenges connected to this transition are twofold: a *pars destruens* focused on the critique of the current economic system, both in its concrete manifestations (such as shareholder value approach, Spitzeck 2009) and in its underpinning theoretical assumptions (Fontrodona and Sison 2006), and a *pars construens* required to outline what should replace such a system (Pirson et al. 2014; Setter and Zsolnai 2019).

To successfully fulfill this two-folded mission, HME has developed three main levels of discussion. The first is the anthropological level, where

HME is defined as a process of community building through business practices and visions: “Humanistic management does not only consider the individual but it aims at building communities because it considers business enterprise to be a community of persons” (Melé 2003: 82). The idea of community is defined by cooperation given anthropological assumptions: “We possess a natural tendency to cooperate, out of necessity in a world of scarce resources and harsh environment but also out of the social nature of human beings” (Schlag and Melé 2020: 1). This vision is opposed to the one of *homo oeconomicus* and of agency theory and seeks to replace it by affirming the validity of the Aristotelian model of the *Zoon Politikon* (Fontrodona and Sison 2006). Moreover, it involves a vision of the human condition that conceptually engage the Arendtian notion of work that should replace the one of labor (Arendt 1958) as well as suggesting that entrepreneurship and management can be conceived as, following Arendt, proper *action*, in its politically and socially engaged aspects. This vision tries to answer to the “Why” doing business in a humanistic driven way is possible.

The second level tackled by HME is the epistemological level concerning how this paradigm can be understood in the light of previous debates in the field and how it allows to overcome updated business visions that are not able to cope with current crises and challenges (Parente et al. 2018). This level of analysis sheds new light on humane entrepreneurship as a practice influenced by a global strategic posture: “the understanding of entrepreneurial strategic behavior, encapsulating in such a behavior an inclination toward human resources, nature, and society” ((Parente et al. 2018). This vision tries to answer to the “How” humanistic based business models can be organized within the current economic system.

The third level of analysis is the one aiming to provide, through HME approaches, pressure to reform the economic discipline starting from business studies and business ethics contributions (Dierksmeier 2005). HME is thus conceived as a sustainable, radical alternative to the current mainstream “shareholder capitalism” vision due to the fact that “Such shareholder capitalism is

usually seen as unbalanced and unsustainable” (Spitzeck et al. 2009). This idea entails a scholarly effort to revise the nexus between the microeconomics and macroeconomics dimensions where business studies insist: “With the increasing severity of a multitude of crises, it becomes ever more evident that the dominating Anglo-Saxon model of shareholder centered capitalism falls short with regard to its sustainability and life-conduciveness on a systemic level, organizational level, and individual level” (Pirson et al. 2014). The proposed *pars construens* focuses on affirming that the economic discipline should focus on values as well as on value (Pirson 2017; Dioguardi 2017; Melé 2013). Ever since the cornerstone reflection by Amartya Sen *On Ethics and Economics* has been circulated (Sen 1987) both scholars and business actors have faced the logics of the entanglement of the two spheres. By looking at the firm as a social actor (Solomon 1992; Sacconi 1991) HME rests on the idea that the analysis of its functioning, aims, and needs cannot be reduced to economic performance or competitive advantage, but rather accounts for broader causes and consequences. Both these causes and consequences cannot be investigated focusing on updated notions of value but has to be discussed in the light of values informing entrepreneurial vision, firm culture, workers participation, and other intangible assets.

Indeed, the theoretical framework proposed by HME allows to overcome the traditional vision of the economic discipline as being concerned only with quantitatively measurable and objectively observable variables resulting as outputs of human actions. In line with the scope of its research and with the object analyzed, HME ultimately promotes a qualitative understanding of business interactions. This can certainly lead to critiques and skepticism on the possibility to rigorously approach: “anything that is not objectively observable in human conduct—emotions, beliefs, values, symbolic representations, which are all thought to be of little significance in understanding economic actions” (Screpanti and Zamagni 2005). Nevertheless, the orientation toward a humane economy is growing out of a neglected but longstanding tradition (Jackson

2016; Röpke 1960) and HME posits itself as being the vanguard of a renewed interest in business ethics. Change in paradigms within the economic discipline is more common than is usually understood: As Alfred Marshall argued, the history of economic thought shows that this sphere of knowledge does not progress in a linear way but rather by disruption, revisiting of previous neglected ideas, epistemological leaps. HME establishes itself with confidence that this intuition poses the base for a plurality of approaches and it is the more true for a performative discipline such as business studies are (Locke and Spender 2011; Waddock 2020). Ultimately, the study of business affects the way business is conducted; therefore, the abovementioned twofold effort is undergone by scholars working within HME approach in order to provide accuracy and coherence between theoretical framework, methodology, and object of the study. This last level of analysis tries to answer the “by Who” and “Where” the transition to an economy based on humanistic values can be promoted; indeed, enhancing HME ability to investigate and, at the same time, influence the business sphere, leads to the circulation of this perspective both inside and outside the academia: “Humanistic management is emerging as a response to the economistic paradigm prevalent in today’s business schools, corporations, and society” (Laszlo 2019).

Summary

HME is a recent field within business ethics studies. Its privileged object of study is the humanistic enterprise (as an ideal type as well as in its concrete examples) with its distinctive features, its conditions of possibility of existence subject to certain economic systems and models of capitalism, its desirability as a goal of transition processes from nonhumanistic business models to it, its ways of implementation, and its underpinning motives for adoption and enhancement. Moreover, HME seeks to grasp relevant motives influencing business actors in the choice of pursuing humanistic and virtue-based leadership styles, governance models, and decision-making processes able to balance ethical and profitability

goals, by providing a coherent framework for their description, discussion, and explanation. Indeed, HME provides a paradigm able to evaluate the impact of nonstrictly related economic variables on economic and business behavior, as well as able to argue for a transition from economic reductionism to humanism by focusing on values informing economic interactions. Therefore, scholars involved in HME research are ultimately concerned with understanding whether this paradigm represents a well-designed framework to discuss and explain some praiseworthy exceptions to the maximizing self-interest-based model of the *homo oeconomicus*, or rather it can represent a source of large-scale change in the business sphere.

Definitions

Poverty and hunger are multidimensional phenomena. According to the National Research Council (2006), hunger refers to a life-threatening lack of food or short-term physical discomfort as a result of food shortage. The United Nations Food and Agriculture Organization (FAO) estimates that about 10.7% of the world's total population are suffering from chronic malnutrition (FAO 2017).

Food production is enough to feed the world population. The main problem is that many people in the world still do not have a minimum income level to buy nutritious food for their own. The Hunger Project estimates that about 11% of people are living in poverty and survive on 1.90 USD or less per day (The Hunger Project 2019). According to the World Bank (WB 2019), 1.90 USD or below income level per day is known as extreme poverty. The majority of people in extreme poverty live in rural areas and are poorly educated and under 18 years of age. With hunger, children suffer the most from poverty. Poverty has various forms including lack of minimum level of income and related resources to ensure sustainable livelihood; inadequate housing; discrimination; inadequate access to schools, health care, electricity, and safe water; social and economic exclusion; etc. (The United Nations 2019; The World Bank 2019). Moreover, for those who have been able to move out of extreme poverty, it is usually temporary.

Hunger and Poverty in the World

Almost half of the hungry people live in low-income countries; moreover, Africa (sub-Saharan region) has the highest prevalence of undernourishment, and Southern Asia (including India, Pakistan, and Bangladesh) has the highest number of undernourished population (FAO et al. 2017). Children are the most disadvantaged group experiencing undernutrition. It is estimated that annually about 45% of children die because of undernutrition (UNICEF, WHO, and

WB 2018). It should be noted that undernutrition increases the effect of diseases such as measles, malaria, pneumonia, and diarrhea (world hunger 2018).

Food insecurity also refers to the inability to access foods that are safe and nutritionally adequate. Malnutrition is a condition resulting from insufficient intake of a biologically necessary minimum level of nutrients. In this concept, the focus of hunger is undernutrition (National Research Council 2006). There are two types of undernutrition:

- Protein-energy malnutrition (PEM): lack of calories and protein that are necessary for key body functions. PEM is the key variable when world hunger is calculated.
- Micronutrient: vitamin and mineral deficiency. There are three key micronutrient deficiencies, vitamin A, iron, and iodine (world hunger 2018).

Solutions to Poverty and Hunger

Poverty and hunger and their various forms have become international priorities during the last decade. The 1996 World Food Summit and the Millennium Declaration of 2000 addressed poverty and hunger to achieve sustainable development. Three UN organizations, FAO, IFAD (International Fund for Agricultural Development), and WFP (World Food Programme), have been working to address hunger, poverty, and food security-related issues (FAO 2019). The World Bank Group's mission is also announced as "Our Dream Is a World Free Poverty" (The WB 2019).

Poverty is a crucial cause of hunger. Other major reasons are climate change and natural disasters (Hillestad 2019). The low-income countries are usually unable to deal with these disasters. On the other hand, hunger also causes poverty. Thus, both dimensions are interrelated (The Hunger Project 2019). Solutions against hunger and poverty aim to empower disadvantaged people to improve their access to income and nutritious food. There are several possible

solutions and actions against hunger and poverty:

- Boost women's economic impact and labor force participation rate.
- Help implement microfinance programs, subsidies, funds, and grants.
- Introduce income-generating activities and training to increase household income.
- Provide agricultural support (The Hunger Project 2019).
- Provide cash transfer or cash for work programs.
- Health and nutrition programs provide training on signs of the illness early and help to prevent malnutrition (Action against Hunger 2019).
- Food aid and school feeding as a form of food aid.
- Closing the resource gap: policies and resource mobilization issues at the national level.
- Nongovernmental organizations (NGOs) to addressing poverty and hunger.
- Corporate social responsibility (CSR) projects (FAO 2019).
- Investing in human capital through education, health, family planning, and nutrition (Binswanger and Landell-Mills 1995).

Summary

Poverty and hunger are multidimensional phenomena. They are inseparably linked with each other. The poverty is a crucial cause of hunger and the hunger is able to be considered a factor of extreme poverty. The rural households are the reflections of the consequences of phenomena. Poverty and hunger and their various forms have become international priorities during the last decade. The specialized organizations deal with these issues in an urgency.

Hybrids

Definition

The term hybrid refers to those organizations that combine different institutional logics and/or organizational forms and identities in an unprecedented way (Battilana and Dorado 2010).

Institutional logics are meant as socially constructed and historical patterns of assumptions, practices, values, beliefs, and rules by which people provide meaning to their daily activities (Ocasio 1997; Suddaby and Greenwood 2005; Thornton 2004), guiding actors' behavior in activities. Examples of institutional logics are the market, social development, economic sustainability, medical professionalism, etc. (Greenwood et al. 2010). Practical manifestation

of one or more legitimated institutional logics results in an organizational form which is characterized by structures and practices within an institutional context (i.e., commercial business, public organizations, private charities, etc.) (Haveman and Gualtieri 2017).

Hybrids are those organizations that pursue contradictory institutional logics (goals) and/or do not fully fit into established categories of organization forms (i.e., commercial business, public organizations, charities, etc.). Typical examples of hybrid organizations are those operating simultaneously in social/environmental and economic fields such as microfinance banks, cooperatives, hospitals, social entrepreneurship, etc. (Boyd et al. 2017). Social enterprises that combine charity to business have recently been widely studied by scholars (Mair and Marti 2006; Seelos and Mair 2005).

Managing hybrids presents many challenges because of some peculiar conditions under which they operate, such as the presence of a wide variety of stakeholders, the tension of the organization toward different, and often conflicting, goals, and the its engaging in divergent activities (Alexius and Staffan 2019). Hybrids struggle to balance multiple interests and goals at the organizational level, within forms of organization whose boundaries are not always unambiguously defined.

Hybrid organizations have the peculiarity to operate by mixing different institutional logics and/or distinct organizational forms (Battilana and Dorado 2010; Pache and Santos 2013; Mair et al. 2015).

Institutional logics are socially constructed and historical patterns of assumptions, practices, values, beliefs, and rules (Haveman and Gualtieri 2017; Ocasio 1997; Suddaby and Greenwood 2005; Thornton 2004). Actors use logics to give meaning to the activities they perform in every situation. When studying organizations, the logics represent the objectives to which the organization aims (Haveman and Gualtieri 2017). Social development, profit, market, economic sustainability, etc., are just some examples of a very large number of institutional logics currently in existence (Greenwood et al. 2010). The particularity of

hybrid organizations is that they struggle to address multiple institutional logics at the same time. For example, hybrids have the capacity to bond traditionally for-profit logics with traditional nonprofit logics (Pache and Santos 2013).

Organizational forms (Dart 2004), on the other hand, represent consolidated practices that result from the adoption, within a specific context, of one or more logics (Thornton 2004). For example, an entity can assume the organizational form of a non-for-profit enterprise as a result of practices and routines aimed at pursuing a “social development” logic as main organizational goal. Historically, organizational forms such as commercial businesses, public organizations, and private charities embraced distinct organizational forms. The boundaries between organizational forms were sharp, and there was a close connection between the type of organization and its form. Commercial businesses, public organizations, and private charities were associated, respectively, with the private, public, and nonprofit sectors (Doherty et al. 2014).

Hybrid organizations, as mentioned, do not embrace a single, defined organizational form. On the contrary, their distinctive feature is that they use a “hybrid” organizational form (Battilana et al. 2017). The reason for this organizational form hybridization lies in the fact that they respond to different, and sometimes conflicting, institutional logics (Greenwood et al. 2010; Thornton 2004). Consequently, the emerging organizational forms should have eclectic nature in order to address different logics. For example, a hybrid organization, in order to pursue both social and economic goals, can mix private charities with commercial business forms and vice versa.

The recent interest in hybrid organizing arises from the increasing number of entities that, pursuing different goals, combine aspects of multiple organizational forms (Ménard 2004). Indeed, in recent years, there is an increasing number of organizations whose mission is not alternatively economic or social/environmental but a mix of the two. In this sense, for example, there are for-profit organizations that engage also in social and environmental issues and, on the other hand, many social organizations aiming to reach economic

sustainability in order to preserve their ability to provide welfare services to the community in the long term (Battilana and Dorado 2010). There are many examples of such organizations (Boyd et al. 2017). State-owned enterprises may also compete on the marketplace for economic sustainability reasons. Microfinance organizations are a fast-developing phenomenon that aims to combine the banking with the social development logic. There are many hybrid organization examples in the social housing and hospital business in which social and economic purposes are mixed together (Battilana and Lee 2014). Social entrepreneurship combines traditional for-profit entrepreneurship with a mission to change society (Mair and Marti 2006; Battilana et al. 2015). It offers new ideas on how to stimulate for more socially sustainable and acceptable business strategies and forms of organization that contribute directly to sustainable development. It also suggests the tendency of corporations to take on great respect social responsibility in order to achieve the common good additional returns for shareholders.

According to many scholars, hybrid organizations are likely to achieve greater social and economic targets as they combine competencies and perspectives of many different logics. In this sense, the abundance of different prospective and views represents a valuable asset and a competitive advantage over the mono-focused entity. The result is expected to be higher value, and the organization is stronger to meet the challenges in the long term (Battilana and Dorado 2010).

Generally, societies measure the performance of organizations and reward those that generate value while remove those that destroy it. The logics beneath the actions of hybrids, because of their multifaceted and divergent nature, make it very difficult to measure the value generated by the organization and, consequently, can lead to biased assessments. As a result, the community does not always have the instruments to measure which entities are destroying value and how to exclude them (Mair and Marti 2006). The issue of measurement of performance within multi-mission organizations is a much-debated issue precisely because of its complexity and its impact on social value. Furthermore, due to the difficulty

of performance measurement, hybrids can be challenging to manage (Alexius and Staffan 2019; Ebrahim et al. 2014; Lauesen 2016; Mair et al. 2015). The different and contrasting missions addressed by hybrids result in unclear actions to be undertaken. The presence of multiple stakeholders complicates the mechanism through which decisions are taken and can lead to inactivity and inefficiency. In this sense, the management of hybrid organizations should be composed mostly by skilled professionals as they are expected to be able to balance between contrasting interests and goals (Pache and Santos 2013). Indeed, it is not easy to estimate the general value produced by the organization when one indicator is reduced in favor of the increase of another.

In some cases, the process of “hybridization” of organizations is processed by commercial companies merely for symbolic reasons (Pache and Santos 2013). However, the majority of hybrid companies originate because the complexity of the market requires to address multiple matters at the same time. For example, a performing case of hybrid organization is the microfinance phenomenon. Microfinance banks provide small loans to needy people who could never reach the traditional credit market. By combining social and banking logics, microfinances capture an otherwise unserviceable slice of the market (Battilana and Dorado 2010).

Insights for Future Research

Future research on hybrids should focus on the development of the still undiscovered areas of this model and on the implementation of methods to overcome their evident limitations.

There is a need to deepen the model of the hybrids in the different geographical contexts, investigating whether there are territorial peculiarities that can influence their development and structure. In addition to territorial differences, it is interesting to study if and how the organizational model of hybrids is influenced by the nature of the different objectives pursued.

It is important to go deeper into the issue of governance and management of hybrids which, as

seen, is a highly complex aspect due to the vague character of the focus on organizational objectives. The issue of measuring the performance of hybrids is an extremely crucial issue in determining their social role in generating value (social, economic, and environmental). In addition, measuring the nonfinancial performance of hybrids is a fundamental tool to overcome the problems of debate around how to balance the different and conflicting interests involved in hybrid organizations.

Summary

Typical examples of hybrid organizations include microfinance banks, cooperatives, hospitals, social entrepreneurship, charities, etc., which operate concurrently in social/environmental and economic fields. Hybrid organizations pursue contradicting institutional logics (goals) and/or do not entirely fit into predetermined categories of organization structures (i.e., commercial business, public organizations, charities, etc.). Hybrids can combine conventionally for-profit logics with traditionally non-profit logics and reorganize organizational forms in unexpected ways. Due to the peculiar conditions under which hybrids operate, such as the presence of a wide variety of stakeholders, the mixed organizational form, the organization’s tension toward different and frequently conflicting goals, and its divergent activities, hybrid management presents numerous challenges. In practice, the measuring of performance within multi-mission companies is a highly disputed topic due to its complexity and impact on societal value. Additionally, hybrids might be tricky to maintain due to the difficulties of performance measurement. The opposing and dissimilar missions conducted by hybrids result in ambiguous measures to be made. However, most hybrid organizations are founded because the complexity of the market necessitates addressing many issues simultaneously. A successful example of a hybrid organization is the microfinance phenomenon. Future studies on hybrids should concentrate on the governance and management of hybrids, which is a

highly complicated element due to the ambiguous nature of the focus of the organizational objective. Mainly, monitoring the performance of hybrids is a critical factor in determining their social role in generating value (social, economic, and environmental).

Impact Assessment

Daniela Lud
Faculty of Communication and Environment,
Rhine-Waal University of Applied Sciences,
Kamp-Lintfort, Germany

Definition

Impact assessment is an overarching concept and can generally be defined as a systematic procedure to evaluate the consequences of an action or plan which has been or will be performed (IAIA 2009; Lawrence 2013). Other definitions focus on the facilitating role of impact assessment, as it leads to better decision-making by providing information to identify, predict, and evaluate the effects of an

action, plan, or project (Smith 2014). In an impact assessment, the situation with an implemented action or plan is compared to a situation without the action or plan implemented.

Impact assessment as a general overarching concept can be applied in various contexts mainly to analyze data and integrate scientific results into decision-making. Furthermore the technique can be used within regulatory frameworks, according to guidelines or as a process management tool to improve a project, plan, or program.

There are different kinds of impact assessments; these include among others Environmental Impact Assessment (EIA), the oldest form of impact assessment with a focus on environmental consequences of projects or plans; Regulatory (or policy) Impact Assessment (RIA), assessing the impact of newly proposed regulations or policies; Strategic Environmental Assessment (SEA), an impact assessment on the strategic policy, planning, and programming level; Sustainability Impact Assessment or Sustainability Assessment (SA), accounting for an integrated assessment of the three aspects of sustainability; and Social Impact Assessment, mainly aiming at the evaluation of social aspects.

Introduction

In the 1960s and 1970s, the awareness of the growing impact of human activities on environmental resources at a local, regional, and global level increased. In 1970 the National Environmental Policy Act became effective in the United States and set a formal procedure for EIA as one of the oldest types of impact assessment (Glasson et al. 2012; Morgan 2012). Similarly, a European Directive on EIA triggered an increased application of EIA in European countries so that to date most countries have national and/or regional EIA systems and regulations (IAIA 2009).

At present the general concept of impact assessment is widely applied in various forms. Impact assessment procedures were established with the primary aim to provide detailed information about the consequences of proposed interventions in numerous sectors. The data supplied can support the decision-making process, and, if required, suitable follow-up actions can be derived. An illustration of the variety of general applicability of the concept for decision-making is given in Fig. 1.

Impact Assessment, Fig. 1 Outline of impact assessment as a general systematic procedure to evaluate the consequences of a range of planned actions with a variety of aspects to consider

Approaches and Types of Impact Assessment

There are different approaches to impact assessment (IAIA 2009). The technique can either be used as:

- An analytical tool to analyze effects of an action, project, or plan gathering and preparing information for a better, more evidence-based decision-making process.
- A formal tool within a legal or regulatory framework. If performed as a legally required instrument, the application of the method can be strengthened. However if the procedure is carried out merely to fulfill formal requirements, this can affect the quality of the outcome of the assessment procedure (Morgan 2012).
- A process management tool to improve a project, plan, or program. From the start of the project, plan, or program, stakeholders and target groups can be involved in the process; thereby the assessment can contribute to an overall sharpening of the objectives of the project and can improve participation of stakeholders and target groups during all stages of the process.

A growing number of new forms of impact assessments are applied in various sectors. They differ with regard to their subject and can range from biodiversity impact assessment to social impact assessment. There is also a diversity with regard to the width of scope, which means that an EIA can be performed with a narrow scope on biophysical environment or with a wider scope including social and economic aspects, for example. Furthermore some impact assessments can be limited to a specific aspect or target an individual project only, whereas others can have a higher level of integration and evaluate strategic alternatives. An EIA can be performed with a focus on the project level in opposite to an SEA with a focus on strategic decision-making regarding programs or policies (Glasson et al. 2012; IAIA 2009; OECD 2010).

As depicted in Fig. 2, frequently used types of impact assessments include, but are not limited to, the following:

- EIA, an assessment of the environmental consequences of a project, plan, policy, or program, prior to making a decision on the implementation of the action proposed (see chapter on Environmental Impact Assessment)
- SEA, an assessment on the strategic level directed toward integrating environmental, economic, and social aspects effectively in plans, programs, or policies (see chapter on Strategic Environmental Assessment)
- RIA (Regulatory Impact Analysis or Regulatory Impact Assessment) a form of assessment evaluating positive as well as negative consequences of new regulations and policies
- Sustainability Assessment (SA), sometimes also referred to as Sustainability Impact Assessment, an integrated, non-sectoral assessment on a strategic level addressing economic, environmental, and social consequences of policies, plans, or programs (Bond et al. 2012; OECD 2008).
- Social Impact Assessment (SIA), a specific, sectoral type of impact assessment with a focus on social aspects
- Biodiversity Impact Assessment, an impact assessment integrating biodiversity conservation and equitable, sustainable use of biodiversity into impact assessment (Geneletti 2016)
- Life Cycle Impact Assessment (LCIA), a form of impact assessment performed as one of the phases of life cycle analysis (Hauschild and Huijbregts 2015)

So the variety of approaches and types of impact assessments is large. Regarding the principles of impact assessment in practice and quality criteria, issues relevant to impact assessment in general can be identified. Important key principles of impact assessment are transparency, efficiency, and proportionality. Several authors have addressed the role of quality in the field of impact assessment (Bond et al. 2018; Morgan 2012). For impact assessment to be effective – i.e., impact

Impact Assessment,

Fig. 2 Types of impact assessment, depending on context differing in focus and or width of scope. Sustainability Assessment and Strategic Environmental Assessment are more comprehensive and more integrated types of assessment; Health Impact Assessment and Social Impact Assessment are more specific and more sectoral types of assessment

assessment improving a process, action, or outcome – several dimensions of impact assessment quality can be identified including efficiency which implies reaching good outcomes under given conditions and in compliance with regulatory specifications. An additional proof of a good quality will be the fact that stakeholders perceive the process or outcome as reliable and are enabled to change and learn (Bond et al. 2018).

Impact Assessment as a Concept to Support Sustainable Development

Impact assessment is well established worldwide, especially in form of EIA and SEA (Morgan 2012). In many countries both a steadily developing legislative basis and an increasing support of science-based decision-making enhance the use and quality of impact assessment. A large number of guidelines and practitioners' documents are available (see, e.g., the website of IAIA, <https://www.iaia.org/resources>).

While initially a large proportion of the forms of impact assessment was rather specific and sectoral (e.g., EIA with a strong focus on impacts on the biophysical environment), more recently developing “new-generation” impact assessments such as SEA or SA are more comprehensive, which reflects the growing awareness of sustainable resource management and sustainable development across communities, sectors, and generations (Bond et al. 2012; Smith 2014). Growing pressure on natural resources and challenges of equity within and between generations creates a need for new concepts of impact assessment (Smith 2014; Morgan 2012). New forms of impact assessment are evolving.

However, in practice, strong interests in economic growth potentially impair the protection of environmental resources. If environmental, social, and developmental issues are difficult to combine in an acceptable way for all stakeholders, integration of different aspects of sustainable development remains challenging, and more guidance might be required on how to

achieve sustainable development through prioritizing adequately (Riley 2016). Seeking a good balance between the three aspects of sustainability and avoiding a simplistic trade-off of one of the aspects requires continuing attention.

Current trends to improve future impact assessment also involve procedures which are more adaptive, deliberative, and participative (Lawrence 2013). New impulses emerge in the fields of collaborative rationality like better ways of dealing with differences in the level of knowledge and the accessibility of information among stakeholders (Bäcklund et al. 2010; Morgan 2012). In the European Impact Assessment System, a collaborative generation of knowledge is already implemented in guidance documents and needs to be put into practice increasingly. Due to the growing plurality of stakeholders, different types of knowledge have to be integrated in the impact assessment process. This growing plurality also makes it more likely that important aspects of sustainability will be covered. This way impact assessment can be a collaborative trajectory of participatory learning and support sustainable development (Bäcklund et al. 2010).

Summary

Impact assessment is a systematic procedure to evaluate the consequences of an action or plan which has been or will be performed. There are a growing number of types of impact assessment differing in the issues addressed, the width of scope, and the level of integration. More recently evolving types of impact assessment are characterized by a wider scope. They are more comprehensive and integral to facilitate the decision-making in sustainable development.

Description

While there is a rich body of research in the area of diversity, inclusion has emerged as a fairly recent area of exploration (Nair and Vohra 2015). Some researchers argue that recently there has been a shift from diversity to inclusion in the workforce of the twenty-first century (Hays-Thomas and Bendick 2013). Eventually, both diversity and inclusion have become recognized as instrumental in improving business outcomes. One could argue that diversity and inclusion complement each other when it comes to improving business outcomes.

While diversity's primary focus is the composition of organizations and teams, inclusion's primary focus is taking the composition one step further and encouraging mixed groups to actively participate and be involved in organizations' activities and decision-making (Roberson 2006; Nair and Vohra 2015). Hence, inclusion can be described as "the degree to which an employee is accepted and treated as an insider by others in a work system" (Hope Pelled et al. 1999). Inclusion is an active process of change or integration, as well an outcome, such as a feeling of belonging, indicating that it is both a process and an outcome associated with it (Deloitte 2013).

Inclusion Framework for Uniqueness and Belongingness

Shore et al. (2011) introduced a 2×2 framework for inclusion to propose both uniqueness and belongingness as main parameters that create feelings of inclusion in the employees (See Fig. 1).

According to this framework, low belongingness and low value in uniqueness result in exclusion, where individual does not view himself or herself as an insider to the organization. Assimilation outcome is achieved with high belongingness and low value in uniqueness where an individual feels like an insider and conforms to the dominant culture. Differentiation outcome is achieved with high value in uniqueness and low belongingness where they are not treated as insiders, but their unique contribution is seen as valuable for the organization.

According to the authors, only high belongingness and high value in uniqueness create the feelings of inclusion where the individual views himself or herself as both an insider to the organization and unique within the work group.

This framework shows the complexity of inclusion since it involves the feelings of individual employee and highlights the fact that diversity alone cannot be sufficient to result in inclusion feelings.

	Low Belongingness	High Belongingness
Low Value in Uniqueness	Exclusion Individual is not treated as an organizational insider with unique value in the work group but there are other employees or groups who are insiders.	Assimilation Individual is treated as an insider in the work group when they conform to organizational/dominant culture norms and downplay uniqueness.
High Value in Uniqueness	Differentiation Individual is not treated as an organizational insider in the work group but their unique characteristics are seen as valuable and required for group/ organization success.	Inclusion Individual is treated as an insider and also allowed/encouraged to retain uniqueness within the work group.

Inclusion, Fig. 1 Inclusion framework, Shore et al. (2011)

Summary

Although inclusion has emerged as a recent area of exploration (Nair and Vohra 2015), it is evident that there is significant shift into this area in the literature. One body of research highlights the impact of inclusion on the organizational performance and business outcomes.

Ferdman et al. (2010) argue that collective feeling of inclusion in an organization is positively associated with group performance indicators, and this relationship is moderated with the diversity of group's membership. Empirical study by Sabharwal (2014) proposes that diversity alone is not sufficient to improve workplace performance and that workplaces become productive only if employees can freely express their opinions and when employees eventually contribute to the decision-making in their respective organizations. According to Mor Barak (2022), employee perception lies within the inclusion-exclusion continuum, and employees get involved in both formal and informal decision-making.

In today's competitive business environment, firms focus more on the sustainable growth and look for different and creative ways to generate profit and stay competitive. Within these lines, gender diversity and inclusion has become a significant research area as women workforce is becoming a more critical human capital for firms to achieve sustainable growth. The firms that tap into this human capital can reap significant benefits in the long run. According to Boston Consultant Group's (BCG) study in 2017, innovation of a firm will jump from 15% to 25% if women managers' proportion increases by 20%. Bersin by Deloitte (2017) surveyed 245 global organizations and concluded that inclusive organizations are eight times more likely to achieve better business outcomes, six times more likely to be innovative and agile for change, three times more likely to be high performing, and twice as likely to meet or exceed financial targets. This study reinforces the fact that diversity, coupled with inclusion, leads to better and more sustainable business outcomes.

Diversity and inclusion require a change management and process in organizations' culture,

and it cannot be achieved overnight. The leaders in the organization should "lead by example" and encourage an open environment where employees can feel confident and inspired to express their respective opinions and ultimately contribute to both short-run and long-run decision-making in their organizations. With this culture change, organizations can build strong foundation to make sure that the business outcomes are sustainable and long-lasting.

Definition

A holistic perspective and the joint efforts of a multitude of actors (institutions, public organizations, private companies, and the civil society) are necessary to tackle with the huge and complex phenomenon of poverty (Narayan-Parker 2000). A large portion of the world population, especially in developing countries, lives in poverty and is grappling to attain the most basic needs (food security, access to water, health, and education).

The concept of inclusive business (IB) dates back the early 2000s and was initially used in the context of the pro-poor growth agenda. It was coined by the World Business Council for Sustainable Development to refer to business models capable of incorporating the objective of human suffering alleviation, in pursuing their activities (Prahalad and Ramaswamy 2004). Both scholars and practitioners have provided several definitions of inclusive business. The former have defined inclusive business as accounting for

human dignity or human rights considerations in businesses (Ioannou and Serafeim 2012). Practitioners and institutions have emphasized inclusive business viability in providing a living wage for vulnerable groups while enabling buyers to profit and the poor to escape from poverty. The concept progressed with the world debate on the fight against social and economic inequalities within the sustainable development umbrella and the current global agenda whose Goal 1 “No Poverty” addresses the urgent need to “end poverty in all its forms everywhere” (UN 2015).

Introduction

Inclusive businesses contribute to benefit low-income inhabitants and their communities and, more generally, increase opportunities for the disadvantaged and indigent. Through the engagement of “people living at the bottom of the economy” (Gradl and Kenkins 2011, p. 5), inclusive businesses generate high development impact by improving access to goods and services and/or providing income and/or employment opportunities to low-income people – that represent the base-of-the pyramid population – as producers, suppliers, distributors, employers, or employees (ADB 2020).

In order to leverage their responsible and sustainable business model, companies are called to generate corporate shared value, the latter encompassing economic, environmental, and social value. A concrete way to create shared value rests on contributing to fight poverty, overcoming traditional approaches based on business philanthropy, or the involvement of public authorities. Several studies have pointed out the importance of the co-creation of value and suggested collaborative actions of the private and public sectors and non-governmental organizations (McDermott et al. 2009; Mair and Marti 2009) to promote activities at a micro-level (Tracey et al. 2011; Peredo 2003) aimed to eradicate poverty. In this vein an inclusive business underpins a sustainable business model “that seeks to productively engage income-constrained groups in the value chain by providing solutions to neglected problem, such as poverty”

(Schoneveld 2020, p. 8). Hence, it generates inclusive innovation and creates opportunities by overcoming economic, social, environmental, and geographical barriers (Likoko and Kini 2017; WBCSD 2008; Anderson and Billou 2007; Mair and Seelos 2007; UNDP 2008; Karamchandani et al. 2009; Jenkins et al. 2010). According to this perspective, inclusive businesses enable the inclusion of the base of the pyramid (Prahalad 2004) in the business's value chain through financing, adapting products, and distributing goods and services (see: IFC 2012, p. 3). This orientation can in fact be operationalized into several ways and areas, for instance, by integrating a company's supply/distribution chain with underprivileged producers, collaborating with the producers of natural raw materials and handcrafted products, stimulating community-based entrepreneurship, and by preserving their natural environments.

Key Issues

A useful guide encompassing several successful inclusive business experiences was provided by The Endeavor Report (Gradl and Knobloch 2010) that explains how companies can increase their competitiveness through generating new business ideas (Jenkins 2007; Berdegúe et al. 2008) that address huge and wicked problems. Drawing from these experiences, among the benefits are the coverage of essential needs, a growth in productivity and income, and the empowerment of poor people.

On the one hand, inclusive business models offer jobs, food, access to water, electric power, medical provisions, housing, and education to low-income people, as well as access to the Internet and financial resources (i.e., loans and insurance). In developing countries these provisions improve the living conditions of people and enable the creation of business opportunities for craftsmen, farmers, and micro-enterprises.

On the other hand, companies can strengthen their competitiveness in many ways: by setting up supply markets and growth-intensive sales that can benefit from population growth and increase

income; accessing alternative supply source of raw materials; creating innovative products/processes; increasing reputation and loyalty of suppliers, customers, investors, governments, and the community; leveraging on local skills and traditions. For instance, an inclusive business model can be founded on contract production systems that obtain resources from small-scale farmers. Moreover, the plentifulness and variety of unrefined raw materials makes it possible to improve the supply chain and satisfy the quality standards for "organic" or "fair."

Large globalized and multinational companies (MNCs) can actively participate in mitigating poverty (Basu 2001; OECD 2001). Their contribution has attracted the attention from the political and scientific community (Kolk and van Tulder 2006) due to their expected leading role in partnering with governmental and non-governmental institutions to transfer expertise and knowledge and improve socio-economic conditions, training, and equal opportunities in poor countries. The first guide of World Business Council for Sustainable Development resulting from the "Sustainable Livelihoods Project" (WBCSD 2007) pointed out that "doing business with the poor allows multinational companies benefit from potential new market, while contributing to improve their living conditions." Therefore, their approach could mirror opportunistic-led or authentic-driven orientations. Several multinational corporations started to implement inclusive business models under institutional pressures and/or solicited by stakeholders – including other competitors – thus following a mimetic process. In some cases, they moved to inclusive business model after prior irresponsible conducts, and are not candid about poverty alleviation, thus eliciting criticism (Stiglitz 2002). Moreover, their conduct has been criticized since only a few issues relative to poverty have been addressed. Creating value through solutions to neglected problems is effective when multinational companies overthrow the logic of "single approach." Effective solutions are based upon supplying the poor with "tools" (resources, know-how, and technology) useful to break them from poverty, creating an enabling environment that facilitates dialogue and actions

with local actors and actively including poor local communities (Kolk and van Tulder 2006).

Furthermore, beside large and multinational companies, also small and medium-sized enterprises (SMEs) can play a relevant role in poverty eradication, especially when they manifest a high level of embeddedness to their local area (Storper 2005). SMEs are a fundamental part of the local socio-economic fabric and are connoted by a high degree of social and relational capital. In many cases, they reduce poverty in their territories by offering jobs, training, and environmental requalification. In doing so, they contribute to avoid degradation or depopulation. A true dedication inspires values-driven SMEs, which takes place through networks with local actors and relationships that enable businesses to connect with the local and extra-local context, rich in tangible and intangible resources (Del Baldo 2010; Del Baldo and Demartini 2012).

Several authors have stressed on the imperative of acting at the local level, especially in underdeveloped countries, favoring the set-up of community-based enterprises (CBEs) to enhance the interaction among communities and families that are embedded in local social structures (Peredo 2001, 2003). Community-based resolutions are fundamental to safeguard the environment and generate income among poor communities (Tenenbaum 1996; Lyons 2002; Nelson 2000). “Community-based enterprises pursue the economic and social goals of a community in a manner that is meant to yield sustainable individual and group benefits over the short- and long-term” (Peredo and Chrisman 2006, p. 4). Leveraging on local skills and resources, community-based enterprises represent an encouraging solution and an alternative model to develop local areas in poor countries.

Moreover, benefit corporations (B-Corp) and certified B-Corp can be considered an emerging model of inclusive business. A Benefit Corporation is “legally a for-profit, socially obligated business, with all of the traditional corporate characteristics but with explicitly stated societal responsibilities” (Hiller 2013, p. 287). A B-Corp is an organization that meets specific socially responsible standards assessed by a certification entity named B Lab. The

B-Lab certifies organizations that voluntarily meet the highest social and environmental performance standards, transparency, and accountability through the benefit impact assessment (BIA), a score (ranging from 80 to 200 points) attributed to companies’ performance across five broad categories: environment, employees, customers, community, and governance (Hiller 2013; Nigri and Del Baldo 2018). An organization can obtain the B Lab’s certification without becoming a BC. In other words, the benefit corporations and certified B-Corp are for-profit companies that pursue general and specific public benefits and economic goals. Through their activity, not lucrative and lucrative purposes are in balance. Their diffusion, especially in the last decade, is attracting the interest of the scientific, political, and managerial world (Del Baldo 2019; Nigri et al. 2020). These hybrid organizations (Gamble et al. 2020) rest on regenerative and inclusive business models that entail a purpose-driven orientation in that they are aimed to pursue benefits to be shared with stakeholders, including people on the edge of society and poor communities.

Future Directions

Both the scientific and political community have stressed the urgency to act at the local level to reduce poverty and safeguard the natural environment. Every business can contribute to pursue this goal by adopting a variety of inclusive business practices useful to fight poverty and enhance sustainable local development. The so-called “shared value” (Porter and Kramer 2011) is the outcome of policies and operating practices that re-connect the company success with social and environmental progress. In this regard, inclusive business models increase the company’s competitiveness, while simultaneously promoting the economic and social conditions of communities in which a company operates, thereby extending the link between competitive advantages and social issues. “The societal benefits of providing appropriate products to lower-income and disadvantaged consumers can be profound, while the profit for companies can be substantial” (Porter and Kramer 2011, p. 68).

Summary

Companies can significantly contribute to human development, improving the quality of life of people, especially in developing countries. Fighting poverty through innovative business models provides opportunities for sustainable growth. Inclusive business models are driven by the need to promote dignified humane existence by using market approaches to tackle socioeconomic challenges in a sustainable way (Likoko and Kini 2017). They are characterized by a profitable core business activity that is advantageous to low-income communities and increases opportunities for poor and disadvantaged people. Inclusive businesses – that can be experienced by both MNCs, SMEs, CBEs, Benefit Corporation, and B-Corp – aim to include social responsibility and sustainability in their core business, rather than philanthropy (Gradl and Knobloch 2010). Accordingly, they underpin a stewardship-based approach that calls for enhancing the long-term well-being of a company and its stakeholders by eliminating value destruction through resource depletion and unequal distribution of income and revenues. This can involve transforming value missed into value opportunities (Schaltegger et al. 2016) by repurposing for society and environment.

Definition

Innovation is a phenomenon that concerns the agenda of many disciplines when its developmental process is examined. In today's conditions where change is continuous, considering the changing needs of society, it has an important place not only in the business world but also in social practices, political, and economic fields.

The economic events in the world cause innovation to have an important place in national economies. Beyond just creating economic value, innovation has an important function for companies today. Social problems such as poverty, inequality, climate change, and hunger, which the world is increasingly facing, have become important on a global scale, and the elimination of these problems and the reduction of the effects that will strengthen these problems can be achieved with solutions for social issues. Inclusive innovation focuses on social problems and the innovative solutions that can be found. Inclusive innovation is defined as "the development of new ideas aimed at creating opportunities that enhance social and economic well-being for the disenfranchised members of society" (George et al., 2012). It contains welfare-enhancing efforts for the segment of society that are imprisoned or excluded from innovation and their rights.

What Does Innovation Refer To?

Today, as a result of changing and developing technology, innovation is a concept that constantly affects every aspect of human life and

continues to change and develop. When the development process of the concept of innovation is examined, it is seen that the first definition by Schumpeter (1954) emphasizes the outputs that create a new method, a new quality, a new market, and a new organizational structure. Later definitions of innovation were made based on Schumpeter's definition and different aspects of the concept were emphasized by different researchers. According to Drucker (1985), who emphasizes innovation as a tool of entrepreneurship, innovation is an action that creates a new capacity to provide welfare and provides resources. Porter (1990) emphasized the ability of innovation to create competitive advantage and stated that innovation includes both new technologies and new ways of doing business. Damanpour (1991) defines innovation as the adaptation, development, and generation of new ideas on the success of a firm. Trott (2008), on the other hand, considered innovation from a management process perspective and defined it as the management of all activities involved in the creation of ideas, technology development, the manufacturing process of a new or improved product, or the marketing process from this perspective. The concept of innovation is its basis; it is a concept that completely includes the formation of a new product, service, or process (Brentani, 2001). With this perspective, Hisrich and Peters (2002) defined innovation as the whole of developing a new product or process, creating a new organizational structure, or developing a method. Basically, innovation is the transformation of a new idea into a product that will be demanded in the market and have commercial value (Alpkan et al., 2011). Although there are many definitions of the concept of innovation in the literature, the most accepted definition is still the definition in the Oslo Manual published by the European Commission and the OECD. In the explanations in the Oslo manual, innovation is defined as the realization of a new or significantly improved product (good or service), process, new marketing method, or a new organizational method in internal implementation, workplace organization, or external relations (OSLO, 2005).

An innovative perspective enables companies to gain competitive advantage, increase their market share, and ensure efficiency in their processes. In addition, when viewed from a wider perspective, it has a holistic perspective with its social and economic results in terms of increasing social welfare, sustainable economic growth, increasing employment, and improving living standards, contributing to regional and national development. Therefore, it has an importance that will create a competitive advantage for companies not only economically but also socially. Today, with the increasing awareness of social problems, innovative ideas need to be emerged, implemented, and disseminated in order to solve social problems and meet social needs. Social innovation is a concept that expresses the development and improvement of new systems in solving social problems (Seçkin Halaç et al., 2014). For this reason, the primary goal of social innovation, whose starting point is social problems, is not economic. Therefore, as a result of social innovation, there is an effort to achieve social impact rather than a high profit expectation of organizations (Djellal & Gallouj, 2011). Innovation is about transforming the knowledge acquired or possessed by companies and their abilities in this field into a useful element for society with the help of technology. This transformation can create a social impact when it is about creating useful value in response to social problems beyond just creating economic value. Inclusive innovation, just like social innovation, aims to reveal the positive effects of innovation at the social level and to find solutions to social problems in order to improve the quality of life of societies.

Inclusive Innovation

Since the priority in developing countries is to create economic value, the majority of innovation policies implemented in both the public and private sectors appeal to high-income consumers both locally and globally, and the majority of low-income groups are generally excluded (Mytelka, 2000; KraemerMbula & Wamae, 2010; Fu et al., 2011; Foster & Heeks, 2013).

Albornoz (2013), who argues that the most important reason for this situation is innovation-based inequality, states that innovations with competitiveness-enhancing features result in social exclusion due to the neglect of the wishes and needs of the low-income group in the society (Levidow & Papaioannou, 2018; Patiño-Valencia et al., 2020).

Social structural problems such as inequality, corruption, and social exclusion that arise as technology develops and production and consumption increase are part of the dark side of the system. In recent years, the innovation literature has been trying to analyze, improve, and solve these problems, initially with social innovation and then with inclusive innovation. Since both concepts actually involve innovation, the conceptual similarities with each other are easily noticeable (Patiño-Valencia et al., 2020). The main point where they differ from each other is that inclusive innovation refers to innovations aimed at reducing the exclusion conditions of a certain population, while social innovation is a concept that expresses innovative solutions to a problem that covers the entire society. Although there is a difference between them, both innovations are innovations and improvements that are carried out to increase the welfare of the society. Rosenberg (2004), in his study explaining why technological innovation is the determining force in the economic growth of countries, discussed the most distinctive features of R&D and innovation in countries with developed industrial sectors. These features are remarkable in terms of having effects that increase the welfare level of countries. Considering that innovation practices have a competitive advantage-creating feature for companies, we can say that social inequality has begun to take shape in a different perspective as social inequality has been noticed and given importance.

Inclusive innovation refers to the fact that a group or individuals separated from the general society become a part of the innovation ecosystem by meeting their needs on a particular subject, benefiting from innovations or allowing them to be included in the design and implementation process (Edquist & Hommen, 1999; Müller, 2010; Foster & Heeks, 2013) With the increasing

importance given to inclusive innovation in the past decade, it can be said that the concept has led to the awareness of its effects on academic debates, public policies, and sustainable development. Foster and Heeks (2013) define inclusive innovation as the means by which new goods and services are developed by and/or the lowest-income population. In this context, it emphasizes the importance of the active inclusion of the low-income group, who are excluded from the society, in contrast to the economic value-oriented perspective of traditional innovation (Peerally et al., 2019).

When the inclusive innovation literature is examined, it is possible to list the common features specified in the definitions of inclusive innovation as follows: how important the issues to be addressed from an innovation perspective are for the excluded groups; the extent to which the excluded groups are involved in the development of innovative products; and that innovative products have a significant impact on the livelihoods of low-income consumers (Utz & Dahlman, 2007; Altenburg, 2009; Cozzens & Sutz, 2012; Foster & Heeks, 2013). The common point in the definitions emphasizes the importance of addressing existing social problems and creating social value, especially for communities separated from the general public (Foster & Heeks, 2013; Heeks et al., 2013; Santiago, 2014). Innovation, which is a supporter of technological and economic development, is also the driving force of social change. It also brings social welfare with it. Inclusive innovation, when viewed from this perspective, aims to make innovation studies a mechanism that can meet the needs of all segments of society and can be easily accessed, by giving priority to those who have less resources in accessing innovation, in order to combat global problems such as poverty and inequality, as reflected in the Sustainable Development Goals (Edwards-Schachter et al., 2012). It facilitates access to opportunities, contributes to equality, and aims to improve social and economic welfare (George et al., 2012).

Although studies on inclusive innovation are still in their infancy, it is one of the main topics of sustainable development. Barriers faced by disenfranchised individuals or communities need

to be addressed regularly and resolved through inclusive innovations. For this reason, it is important for academics, policy makers, and the private sector to give importance to ideas that provide inclusive innovation, to help design new ideas, and to help create solutions, in terms of shaping the future and increasing welfare conditions.

Summary

Innovation policies, carried out with the priority of creating economic value, primarily appeal to high-income groups and cause low-income groups to be ignored. Inclusive innovation refers to the fact that a group or individuals who are separated from the general society become a part of the innovation ecosystem by meeting their needs on a particular subject, making use of innovations or enabling them to be involved in the design and implementation process. Considering that innovation policies provide an important competitive advantage for companies, efforts to eliminate problems such as imbalance between income groups and social inequality are increasing day by day and force companies to change with social awareness. Innovation, which is a supporter of technological and economic development, brings social welfare. For these reasons, inclusive innovation aims to make innovation studies an easily accessible mechanism that can meet the needs of all segments of society for the global struggle.

Collaborative leadership; Corporate social responsibility; Inclusive management; Sustainability governance; Sustainability management; Values-based leadership

Definition

Sustainability management includes an approach to governance and leadership which is consistent with the principles of social, economic, and environmental sustainability (Janakiraman 2019; Holliday et al. 2002). The task of a sustainability manager is to overcome competing trade-offs and create equitable situations without compromising one of the components of sustainability (Schaltegger 2012). In the broader leadership literature, the emphasis has been on the traditional model of individual heroic leaders (Crevani et al. 2007) whose character traits and skills (Kouzes and Posner 2017) are correlated with what counts as good leadership. The idea is of leadership as unitary command (Crevani et al. 2007) that is undertaken by an individual who directs the organization in a relatively homogeneous environment and societal context (Bourke and Dillon 2016).

This leadership approach is insufficient for addressing the wicked problems arising from the unsustainability of development based on ecological exploitation and destruction. The idea of inclusive leadership attempts to address the limitations of the heroic approach by identifying capacities and values that are based on distributive models (Gavan 2017; Janakiraman 2019; Tams 2018); collaborative approaches (Bourke and Dillon 2016); and partnering approaches of leadership (Holliday et al. 2002). A central focus of inclusive leadership is co-leadership with stakeholders where diverse opinions and ways of contributing are valued and fostered (Bortini et al. 2016). The key elements of inclusion are: fairness; respect for diversity; nonviolence; belonging; and empowerment (Bourke and Dillon 2016). These elements need to be afforded to all stakeholders, including groups who are challenging the social corporate responsibility credentials of a business.

Introduction

The net effect of the unsustainable business operations of mining and agribusiness entities has seen an increase in global issues of: abuses

of human and nonhuman species rights; environmental exploitation and degradation; and climate change that threatens the survival of island nations, cultures, and Indigenous population (O'Faircheallaigh 2013; Tester 2013). The need for sustainability management is therefore a central matter of concern for all nation states and business entities. Holliday et al. (2002, p. 22) explain that corporate social responsibility involves undertaking transparent governance practices and being open to dialogue with all interested stakeholders. Kouzes and Posner (2017) describe it succinctly when they claim that dialogue is not a monologue and is between equals without exploitation. An emphasis is required on listening, learning, and partnering with impacted stakeholders and managing issues co-operatively (Holliday et al. 2002).

Leadership models have focused on the individual character traits of the person with the implication being that with the right mix of qualities, sustainability managers will be able to implement the sustainability goals of their business entity. Governance is more than a matter of the personal capacities of a leader. Corporate social responsibility issues cannot be collapsed to issues of poor leadership alone. Irrespective of the leader's qualities, businesses that drive capitalist economic development have pursued business as usual and in most cases have avoided accountability for harm done (Butler 2015). For example, changing the local leader of a mining corporation in situations of community outrage (Brueckner and Ross 2010) leaves unexamined the way corporate governance structures are geared towards maximizing profit at the expense of minority group stakeholders (Higgins 2010; Mining, Minerals & Sustainable Development 2002). This power dynamic of business elites gaining at the expense of the public is not restricted to the mining sector. For example, according to Cockburn (2019), the Hayne royal commission (2018–2019) into banks in Australia exposed the blatant disregard for the rights of customers and for the industry regulator. Charges and fees were continued on bank accounts of customers who had died, loans were given to customers without due care to ensure their capacity to repay them, and banks foreclosed

on farmers and other small businesses for dubious and unfair reasons (Cockburn 2019). The Australian Banking Association has been called on to change the industry code to stop banks charging default interest on farmers in drought or in national emergencies (Smethurst 2019).

Inclusive leadership approaches can make a contribution to turning the tide of failures of corporate social and environmental responsibility. Higgins argues that leadership is needed to eradicate the fifth crime against peace, namely, ecocide. Ecocide is defined as:

The extensive destruction, damage to or loss of ecosystem(s) of a given territory, whether by human agency or by other causes, to such an extent that peaceful enjoyment by the inhabitants of that territory has been severely diminished. (Higgins 2010, p. 63)

Higgins suggests that if ecocide is not addressed, this century will be known as a century of resource wars because of the increasing competition and conflict for the limited resources of the planet. A radical shift is required in the governance structures and workplace cultures of business entities to move towards a new paradigm of sustainable progress (Holliday et al. 2002). It is also the case that inclusive leadership in other spheres of society is needed to enable a radical shift in the underpinning capitalist values of competition, the self regulating market, and extreme wealth as the measure of success and value.

The Sustainability Issue

To address ecocide and to achieve sustainable development, leadership in business and civil society needs to be inclusive and framed in terms of social and environmental justice principles. Such a framing rests on a critical awareness of unequal power dynamics and the ability to act fairly and with due awareness of the contextual factors in a given situation. Multinational mining corporations are highly skilled and resourced to protect their interests and at interpreting the legal and political context in which they operate. They know how to use power in their own self interest. A critical awareness of power

challenges how dominant groups exercise their power and at who's cost this might be occurring. Context-sensitive thinking challenges a manager to be inclusive of all stakeholder's interests and to undertake dialogue and negotiations with an all subjected understanding of social and environmental justice. The notion of all subjected justice (Fraser 2009) requires the inclusion of all people who have an interest in, or are being impacted by, the corporation's operations. Further, all parties are considered equal and thus are to have an equal voice in the negotiation of a solution.

One of the difficulties with leaving the task of being socially responsible to corporations is that there is no guarantee they will act in the interests of the public if it is perceived to not be in their interests to do so (Kinley et al. 2007). In Australia, the 2001 Corporation's Act does not require businesses to act in the public's interest and relies on their own interpretation of enlightened self interest (Broomhill 2007). Business managers are legally accountable to their shareholders. They have no legal responsibility to other stakeholders provided they are complying with the laws of the land and licensing requirements. A commitment to inclusive leadership in the resource extraction sector is very complex due to the range of issues related to use of natural, nonrenewable resources for private gain. The operations of mining corporations pose short- to long-term threats to: ecosystem diversity; human and nonhuman rights and well-being; involve issues of land rights (Cleary 2017); and contested claims to natural resources (White 2018). The trade-off for the host society in terms of jobs for its citizens and royalties for the government are often out of step with the extreme wealth that accumulates in the hands of a few elite business owners (Woodley 2020).

Inclusive leadership also ensures all parties are included in addressing matters affecting sustainability and the aim is to act in the public interest without trading the interests and rights of minority groups (Holliday et al. 2002). For this reason, an inclusive leadership approach challenges narrow interpretations of a corporation's legal obligations in their host society and calls for a moral regard for the impact of their business operations. An implication is that managers may often be acting

against their company's interest in the short term. This is a counter intuitive challenge involving the equal valuing of local communities, nonhuman animals, and ecosystems alongside business profits. The moral right to operate in a locality can rest in part on a social license to operate which involves local stakeholders giving their tacit consent and thus giving legitimacy to the business entity (Trebeck 2008). The loss of a social license to operate in ecological conflict situations (Martinez-Alier 2002) can seriously affect the reputation and profitability of a business.

A social license to operate is highly prized by business entities and is often the motivation behind being seen to exercise corporate social responsibility. Bice et al. (2017) describe a public interest model that brings a focus to putting a social license to operate on the map of sustainability leadership. It shows that the challenge of inclusive leadership involves grappling with the intersecting power and contextual factors which pose complex risk and licensing issues for stakeholders. Bice et al. (2017) suggest the idea of a social license to operate is not sufficiently understood and that it may be more complicated than is evident from a cursory glance. They identify the need to critically understand the intersections of social, legal, and political power dynamics and the related vested interests of stakeholders. The ability to think complexly and act fairly where this may not involve wins or pay offs for the dominant stakeholder groups are crucial capacities of inclusive leadership. Naïve thinking by sustainability managers in situations of contestation can reinforce dominant power interests at the expense of other stakeholders. The cost is typically paid by the environment and low-power social groups and localities. Sustainability leadership needs to show how to work this key repressive power dynamic to facilitate different outcomes based on social justice as an integral aspect of sustainability (Ross 2017).

Research shows that the exercise of corporate social responsibility tends to be short-term and philanthropic rather than integrated into the governance and operational systems of companies (Anderson and Landau 2006). In the absence of international code of conduct for business entities

and in contexts of a light touch by regulatory bodies, there is no external accountability for businesses to act in the public interest as well as their business interests. Traditional leadership approaches tend to underestimate the issue of structured inequality of vested power interests which are not immediately amenable to local protests or reasoned arguments. Inclusive leadership approaches, despite their strengths, are also susceptible to being naïve about power.

The shift towards sustainable development needs training in nonviolent and conflict resolution leadership for the public, government officials, politicians, and business managers. It will take a concerted effort of all subjected stakeholders to find ways of addressing the wicked problem. When a society is dependent on industries which are unsustainable and causing harm and injustice, it is an ethical dilemma of major proportions. Sustainability management is everyone's business with each stakeholder group having different orders of responsibility to contribute to just and sustainable outcomes. Ross (2017) argues that the regulatory authority has responsibility to ensure public health, safety, and well-being; the mining industry has responsibility to undertake substantial contributions as part of an expanded notion of corporate social responsibility; and the public have a responsibility to stand together with adversely impacted stakeholders to ensure social justice is achieved.

Summary: Where to Start and How to Proceed?

An inclusive leadership model incorporates the all subjected stakeholders as equals in addressing issues related to the ecological conflict. The underpinning idea of collaboration across differences of power and agendas holds promise for a just, sustainable, and nonviolent way forward. There is a rich tradition of material and a broad range of ways to undertake nonviolent activism in ecological conflict situations (Pickerill 2013; Shaw 2013). For example, Sharp (2005) provides a framework for liberation which draws on a resource of 198 methods of nonviolent action for

activists. The citizenry has had to become well versed in how to mount nonviolent campaigns and protests and international research shows the effectiveness of large-scale mass protests which are nonviolent (Chenoweth and Stephan 2011). The game changer for sustainable management will be when business managers, politicians, the mainstream media, and the elites of society step into a collaborative instead of a combative relationship with socio-environmental activists.

Gandhi believed that true civilization “would promote an expansive sense of trusteeship – or nurturing the world and remembering that as finite beings we never really ‘own’ anything but hold it temporarily as ‘trustees’” (Bakshi 2013, p. 243). The power of love as both a feeling and an action and the related capacity of empathy can make the difference. Gandhi recognized the power of empathy in his efforts to influence the British colonialists during India’s struggle for independence. He understood the change needed would not come from legislators or the “ideological vanguard” but from “an open, ongoing process of voluntary social-cultural transformation” (Bakshi 2013, p. 253).

Inclusive leadership is a context and power-aware approach where the values of justice, love, nonviolence, collaboration, different orders of responsibility, and trusteeship form a shared ethical sensibility for guiding efforts for sustainable progress.

[Financial inclusion](#); [Inclusive finance](#); [Responsible banking](#)

Definition

Inclusive banking encapsulates the systematic approaches adopted to the provision of banking services which ensures that both the services and the processes through which they are developed and distributed are useful to people, communities, and society, do not have detrimental or exploitative impacts, and are nondiscriminatory. Inclusive banking is a more recent addition to the sustainability discourse that builds on but differs from financial inclusion and microfinance (Coetzee 2010). A focus on the practical design of services and the implementation of institutional measures that address the causes of financial exclusion and barriers to financial inclusion allow inclusive banking to combine development concerns with the business of banking. It is therefore a dynamic concept that melds social justice principles, organizational values, and economic considerations. Mainstream commercial banks as well as nonbank financial institutions, telecommunications and digital finance companies, non-governmental institutions, governments, and

regulators all have a role to play in the development of inclusive approaches to providing core banking services. This makes inclusive banking a multi-stakeholder activity that requires consultation, commitment at policy and resource levels, and cooperation. It is not the sole responsibility of banks.

Introduction

Finance has been found to have a pervasive influence on persistent inequality, and there are persuasive arguments for a more inclusive approach to supplying and accessing banking services to transition towards more sustainable financial systems and sustainable growth (Beck et al. 2007a, b; Demirgüç-Kunt and Levine 2009; Demirgüç-Kunt et al. 2017). The Sustainable Development Goals' pledge to leave no one behind emphasizes that issues of equality, inclusion, and non-discrimination are important to development and peace in societies. Banking services provide tools for executing transactions, managing money, accumulating savings and assets, and borrowing to smooth consumption over time. Access to these financial services is seen by policy makers as an enabler of several of the SDGs, because such access enables effective participation in economic activities and creates a pathway to poverty reduction, tackling inequality and promoting social cohesion of individuals (UN Global Compact and KPMG 2016; Klapper et al. 2016; Demirgüç-Kunt et al. 2017; Abor et al. 2018). With increased financialization, pressures for inclusive banking are growing. Financialization is evident in a decline in the number of transactions that are concluded using cash, the widespread use of credit to fund consumption and the importance of individuals' credit history (Martin 2002; French et al. 2011; Appleyard et al. 2016).

Inclusive banking is part of a wider developmental concern with financial inclusion. Indeed, the term inclusive banking has been used interchangeably with inclusive finance and financial inclusion (Ahamed et al. 2018). According to the

World Bank Financial Inclusion Database Index, in 2017, 1.7 billion adults were considered financially excluded worldwide because they do not have an account with a financial institution. Certain groups in society are overrepresented among the unbanked. These include those on low incomes or who face some other type of adverse financial situation or economic vulnerability, women, the disabled, youths, the aged, those who reside in certain localities and regions, and those who are unaware of or do not understand banking options that are available to them (Allen et al. 2016; Demirgüç-Kunt and Klapper 2012a; Atkinson and Messy 2013; Martinson and Martinson 2016).

Inclusive Banking and Financial Inclusion

As a concept, definitions of financial inclusion commonly focus on barriers to financial services, ease of access, the range of products that are available universally, and the cost to consumers of accessing and using these products. Mehrotra and Yetman (2015) simply define financial inclusion as access to financial services. In its widest sense, this would include access to finance for all purposes including transactions, credit, contingency planning, asset accumulation, and wealth creation. HM Treasury (2007) defined financial exclusion as being characterized by having no bank account, no savings, a lack of affordable credit, no assets, no access to money advice, and no insurance. This definition of financial exclusion demonstrates the importance of traditional banking products and of the institutions that supply these products to notions of inclusiveness in finance. Given that ownership of an account with a bank or formal financial institution is a key metric used by the World Bank to measure the degree of financial inclusion in countries, the role of financial institutions, as businesses in crafting and operationalizing solutions to the problems causing financial exclusion, cannot be ignored (Demirgüç-Kunt and Klapper 2012b).

Inclusive banking relates to the business operations and societal impact of all those institutions that undertake the business of banking. The focus on business operations highlights the institutional and practical implementation aspects of inclusive banking. By virtue of their position as the primary formal financial institutions in most countries, banks play an important role in achieving both social and economic inclusion. This can create a temptation to conceptualize inclusive banking quite narrowly as mainstream banking efforts that contribute to meeting the financial needs of the poor and to the goals of poverty reduction and social cohesion. However, as part of the wider efforts to promote the inclusion of all sectors of society into formal financial systems, the business of inclusive banking cannot be taken as exclusive to banks. The ability to provide transaction banking and credit are core retail banking activities, but they are not the sole preserve of banks as a range of nonbank financial institutions (NBFIs) also provide credit and other retail financial services to individuals and small businesses (Corredor et al. 2014; Mader 2018). The types of institutions operating in the inclusive banking space range from banks to NBFIs, nonfinancial firms such as mobile phone operators and digital technology providers, nongovernmental organizations (NGOs), and governments.

Inclusive Banking and Social Responsibility

Inclusive banking is part of socially responsible banking, and many arguments have been presented to provide a justification for institutions to engage with inclusive banking based on good business outcomes (Boyle et al. 2015; Ahamed et al. 2018). While the term inclusive banking, if interpreted loosely, may suggest that all in society should have access, this is a challenging goal because structural factors such as competitive conditions and regulations in different settings may impact on increasing access (Owen and Pereira 2018). The practical implementation of inclusive banking is complex, because the factors underpinning financial exclusion are multifaceted

and the country context is critical to what would constitute inclusive banking in different instances. For example, in developing countries with low levels of educational attainment among the population and poor human development, studies have shown a positive association between years spent in schooling and access to banks (Arora 2012). This suggests that efforts to make banking inclusive need to be complemented with measures for improving education levels, not just financial literacy, among the unbanked to combat demand side barriers to inclusive banking. On the supply side, institutions with a responsibility for and commitment to inclusive banking equally need to educate their staff on the causes and consequences of financial exclusion so that appropriate business policies could be developed.

One of the reasons cited for financial exclusion is information asymmetry. Information asymmetry is a market failure that makes it difficult for the risk of potential borrowers to be evaluated sufficiently by lenders. Consequently, some people have to pay more to borrow or encounter difficulties in accessing credit. Marginalization and exclusion can occur where the policies and practices of institutions that offer banking services do not create equal opportunities to all groups in society in the areas of credit, transaction banking and asset accumulation. It is therefore essential to address these market and banking failures that limit participation in banking for all. Other factors that can exclude certain groups in society and small businesses from credit disproportionately include the extensive use of credit scoring by banks and lack of the type of assets which are deemed acceptable for use as collateral. Microfinance initiatives, like Grameen Bank, emerged to address the need for collateral in conventional banking and to provide access to credit to individuals who would otherwise have no access to formal credit. Schmidt et al. (2016) suggest that microfinance is the antecedent of inclusive banking because like the German savings and cooperative institutions that emerged in the 1800s they served the needs of those excluded from mainstream banking. They see inclusive banking institutions as those which cater to broad segments of the population including those who may currently

have, or at least had, serious problems of access to the well-established institutions. Therefore, when microfinance maintains a focus on credit and on lending to the poorest, it is only a small component of an inclusive approach to banking. In particular, access to transaction banking services provides a means for all groups in a society to carry out day-to-day economic transactions without facing additional costs, removing the poverty premium (Ellison et al. 2010).

Recognizing the limitations of a disproportionate focus on credit, provision of a wider set of basic banking services is the goal of more recent inclusive banking initiatives. In many countries, inclusive banking has become a shared goal between governments and the banking industry usually expressed in terms of a reduction of the number of households or individuals that are unbanked. Initiatives by central banks and governments can support inclusive banking such as policies to make welfare payments direct into bank accounts. The Reserve Bank of India promoted the introduction of basic bank accounts for low-income households in 2005. This was followed in 2014 by the launch of the largest financial inclusion program in the world aimed at including as many unbanked people as possible in the formal financial system by providing them with access to basic banking services (Agarwal et al. 2017). In the UK, basic bank accounts were introduced in 2000 as part of a financial inclusion strategy. These simpler accounts were to be more suited to the needs of the unbanked. The initiative supported a new government policy that introduced electronic payment of benefits and the UK's approach at the time illustrated how the private sector and government could work together to implement inclusive banking (French et al. 2008; Ellison et al. 2010). An inclusive approach to banking that is compliant with social justice principles and economic considerations is important for advanced as well as emerging and developing economies. Societal concerns about banking products relate to how the products meet consumers' needs for quick and secure transactions, liquidity, profitable asset accumulation, access, and protection from any detrimental

consequences that may accrue as a result of using bank products. These products should cater for a range of lifestyles and the widest possible cross section of society. Apart from the design of products, Decker (2004) argues the process by which products are delivered should also demonstrate a socially responsible approach to banking. The use of cost-effective digital means of making banking services available, financial capability interventions, and ensuring that customer information systems support the sale of appropriate products are all important aspects of socially responsible delivery.

Simultaneity and intangibility are two distinguishing features of banking services that create unique challenges to providing access in an inclusive way. Since the production and consumption of services tend to be done simultaneously, the location of banking services was paramount before the advent of technological advances such as online banking (Neuberger 1997). In terms of the access dimension of inclusive banking, the availability of physical as well as nonphysical channels of delivery is an important factor. Delivering banking services through mobile phones, the internet, personal computers, and cards has contributed significantly to the inclusiveness aspect of banking. While the availability of digital channels to banking can make banking more inclusive especially for those in rural areas or those who cannot for other reasons travel to bank branches, this does not always provide convenient and appropriate access (Ozili 2018). There are also concerns that stricter and more comprehensive regulation may be needed to make to make the operations of mobile payments systems sustainable as they develop (Griffith-Jones et al. 2013).

The failure of conventional banking has been found to have exclusionary consequences. Banking failure affects people who had never banked and those who have been previously banked (Ellison et al. 2010). Banking failure refers to a situation where the banks' own strategies and processes result in excluding consumers or have some other detrimental impact on consumers. Steps taken to close branches in rural areas and a lack of the required transport and

telecommunications infrastructure may make it prohibitively expensive to set up a branch resulting in financial desertification (Thrift and Leyshon 1997; French et al. 2008). These have changed the geography of the way in which banking services are provided. Similarly, banks' own strategies of refocusing on more affluent consumers can exclude those without observable wealth. The high cost of some banking products, inappropriate conditions attached to products, and redlining practices are some other factors that exclude some people and businesses (Kempson and Whyley 1999). Begley and Purnanandam (2019) have found that misselling, fraud, and poor customer service have affected those in minority population groups in the USA more than other groups. Redlining, the discriminatory practice by which creditworthy and eligible individuals were denied credit because of the composition of their neighborhoods affected minority populations disproportionately in the USA and was addressed partly through legislation such as the Community Reinvestment Act and the Equal Credit Opportunity Act to make banking more inclusive. Studies suggest that some inclusive banking initiatives and products have hidden burdens, constraints, and other barriers which create negative experiences for consumers and impact adversely on sustainable use of the financial services introduced as part of inclusive banking initiatives (Mowl and Boudot 2014; Ellison et al. 2010; Dupas et al. 2018; Agarwal et al. 2017). Conditions attached to bank accounts such as penalty charges for unauthorized overdrafts or insufficient funds to honor payments could worsen a customer's credit file, making it difficult for them to access banking services at a later. Similarly, lending strategies aimed at the excluded of banks may lead to fast credit growth, result in defaults and then in exclusion, creating a group of those who are "previously banked."

Progress in inclusive banking is made problematic by the many geographical, social, and demographic disparities that exist within and across countries. Furthermore, with demographic and other changes in society, the causes of financial exclusion evolve and present new challenges

to those engaged in designing and implementing inclusive banking initiatives. Studies also indicate that an appropriately regulated environment which caters for protection of consumers and promotes effective competition between providers of banking services is also important for inclusive banking (Owen and Pereira 2018). The benefits of some inclusive banking efforts have been called to question. Microfinance initiatives have been criticized on several grounds, especially that they lead to an unbreakable cycle of indebtedness for users (Scully 2004; Mader 2018). Though economic growth can support inclusive banking by increasing the number of people who technically can become banked, it may not address inequality of opportunity or the poverty premium and other additional costs that some groups in society will face due to financial exclusion or inappropriate financial services. These criticisms contest the widely presented view that financial inclusion is an enabler of most of the SDGs, leading to calls for studies that would explore the causal relationships between financial inclusion, poverty alleviation, and inequality more robustly (Mader 2015, 2018). Furthermore, the evidence on the effects of inclusive banking initiatives is varied and inconclusive. More evidence is needed on the demonstrable impact of inclusive banking and its ability to meaningfully support sustainable development initiatives. Though the benefits of inclusive banking and its contribution are still being debated, a set of defining characteristics of inclusive banking could be outlined as follows.

Key Features of Inclusive Banking

Inclusive banking that is socially responsible and would support the sustainable development goals is:

Anticipatory – Inclusive banking explores and considers consumers' needs and requires those engaged in developing strategies and products to promote inclusiveness to acknowledge and have a good understanding of the problems underpinning financial inclusion.

Nondiscriminatory – Inclusive banking delivers products and processes in an equitable manner so that no group of people is treated in a less favorable way because of race, gender, age, disability, or other factors.

Nonexploitative – While being economically viable for providers, inclusive banking does not penalize or exploit any sector of society and seeks to address the constraints that may make serving certain sectors of the economy a non-viable option. Providers of banking services that adopt an inclusive approach need to ensure that their own practices do not cause harm to consumers and do not result in people becoming unbanked.

Cocreative – Inclusive banking is a process that uses partnership working between different types of financial services providers, governments, policy makers, and third sector organizations to create and deliver appropriate strategies, products and processes that improve access to finance and financial services. Given the complex set of barriers and factors that may cause people to be unbanked, inclusive banking is not the sole responsibility of banks.

Transparent and accountable – Institutions that are inclusive in their approach to banking would be explicit about the values and standards they engage with to deliver their services inclusively. Inclusive banking, by definition, values diversity in its customer base. Institutions should have mechanisms in place that inform on and make it possible to evaluate the range of customers that are served and the impact on customers served. Understanding the social impact of banking strategies and taking steps to minimize these costs as well as build on the benefits is essential to CSR efforts in the inclusive banking space.

Adaptive and corrective – Inclusive banking actively seeks to reduce the barriers to participation that conventional banking practices can have. In that way, it addresses both market failures and banking failures. Institutions are challenged to adopt, as much as possible, an approach that adapts products to meet the needs of those who are

excluded rather than create a separate suite of products exclusively for the unbanked and underserved.

Summary

As access to finance features implicitly in several of the SDGs, the place of inclusive banking in sustainable development should be understood to clarify how financial inclusion contributes to the SDGs. This requires a discussion about the meaning of inclusive banking and the role of different actors in the inclusive banking space. A fundamental pillar of inclusive banking is the recognition that the causes of exclusion are complex and multifaceted. This recognition then needs to be brought into practical inclusive banking initiatives through product governance processes and operations. While 100% inclusion may not be a reality, making banking open to the widest range of people in a viable way is a realistic aim of CSR in banking. As the SDGs pledge to leave no one behind, a significant challenge for institutions engaged in inclusive banking is to monitor, capture, report transparently, and demonstrate the impact of their activities on different dimensions of financial inclusion, different segments of society, and on equality and development.

Definition

Until quite recently, the most important measures to judge the health of the markets and, therefore, the economy have been the Gross National Product (GNP), the Gross Domestic Product (GDP), and the Gross National Income (GNI). Despite the absence of real standardization in this sense, it can be said that these measurements are used by any economic actor to measure the success of economic development: International financial agencies, economists, politicians, financiers, and citizens commonly use these measurements and economic indicator.

Notwithstanding, the current economic literature unanimously believes that GNP, GDP, and GNI cannot represent a perfect measure of well-being. On the contrary, different limits are recognized, including the fact that they measure market activity without taking into account the numerous social costs. This has led several scholars to develop a series of indices to overcome the limits of these monetary measurements and to systematically measure the costs and benefits of growth.

One of the first and most relevant alternative measurements is the Index of Sustainable Economic Welfare (ISEW), which represents an alternative to GDP as it provides an integrated approach for measuring economic development through the simultaneous use of different macro-economic variables together with some social and environmental aspects. In other words, it is a sort

of integrated index of economic development composed of a list of variables that seek to integrate traditional macroeconomic performance measures with some information on social, institutional, and environmental aspects.

Introduction

“Well-being,” as never before, appears to be such a multifaceted, broad, and complex term that any attempt at its possible definition is really arduous, or impossible.

However, in a mere attempt at rationalization, it is possible to distinguish the concept based on two traditional points of observation, or interpretation.

The first, linked to the state of human health, refers to physical or moral strength or, in essence, the “*The state of being comfortable, healthy, or happy*” (Oxford 2019b).

The second, on the other hand, is typically considered part of the economic context, identifying more specifically the concept of “welfare” as the “*The health, happiness, and fortunes of a person or group*” or “*Statutory procedure or social effort designed to promote the basic physical and material well-being of people in need*” (Oxford 2019a).

In this perspective, the latter is responsible for the birth of the so-called “welfare economy,” whose scholars have tried to tackle the problem of how to influence the economic order to increase the well-being of all: hence, the terms “welfare,” “welfare economics,” or “welfare state.”

These two souls of well-being have always coexisted, and this is the central point, even though the economic dimension has always substantially prevailed over the psycho-physical dimension. This aspect is certainly not new and, in effect, is already the subject of some investigative scientific processes (Krippner 2005; Ferlie et al. 2005; Stiglitz et al. 2009; Davis and Kim 2015; Scherer et al. 2016; Ricci and Civitillo 2018; Maiocchi et al. 2019). From them, it appears evident that centralized or “hierarchical” performance evaluation processes (of any type) (Ricci and Civitillo 2018) which depend on the economic-financial dimension or, more generally,

by relying exclusively, or even only on a majority basis, on purely quantitative variables (e.g., money, profit, GDP, etc.), determine the inability to build multidimensional measurement systems. Instead, it is necessary to recognize that any type of performance is intrinsically made up of a plurality of dimensions. Consequently, any process of analysis that contemplates the predominance of a single dimension (or, in any case, of a few variables) with respect to the others should be avoided since the results that derive from them would be strongly conditioned and, therefore, devoid of effective utility. This is even more problematic when it is the financial dimension, based on accounting, which prevails over the other variables. In this sense, conversely, a multidimensional approach becomes necessary to allow an efficient and incisive achievement of integrated and systemic cognitive objectives (Ricci and Civitillo 2018).

On the other hand, it is not useful to renounce utility and relevance of quantitative measurements which, obviously, can only play a significant role in any evaluation system precisely because they are able to confer the necessary “precision,” useful for coming to any judgment. In this sense, the need to use money in the performance of economic measurements cannot be denied:

The one obvious instrument of measurement available in social life is money. Hence, the range of our inquiry becomes restricted to that part of social welfare that can be brought directly or indirectly into relation with the measuring-rod of money. (Pigou 1920, p. 11)

Indeed, it can be argued that it is precisely the instrumental role of money that has led economic science to firmly believe that market performance is the fundamental determinant for creating the well-being of the people who are part of economic systems.

Overcoming Traditional Measurement of Economic Systems: ISEW Index

Until quite recently, the most important measures to judge the health of the markets and, therefore,

the economy have become the Gross National Product (GNP), the Gross Domestic Product (GDP), and the Gross National Income (GNI). Despite the absence of real standardization in this sense, it can be said that these measurements are used by any economic actor to measure the success of economic development (Daly and Cobb 1989): International financial agencies (e.g., World Bank, International Monetary Fund), economists, politicians, financiers, and citizens use these measurements and economic indicator every day and systematically for economic, absolute, and comparative judgments.

Notwithstanding, while recognizing the importance of quantitative analyzes in economics and of the fundamental role played by the instrument of money, the current economic literature unanimously believes that GNP, GDP, and GNI cannot represent a perfect measure of well-being or of welfare. On the contrary, different limits are recognized, including the fact that they measure market activity without taking into account the numerous social costs. In this perspective, for example, some studies have shown that people's level of happiness does not depend solely on the average level of national income: in fact, it can also increase by reducing the range of income distribution (Hagerty 2000). Nevertheless, the real problem is that, very often, these same weaknesses are considered not particularly relevant or in any case not so serious as to undermine the informative power of such measurements which, therefore, are commonly used to express judgments about well-being in many contexts (Daly and Cobb 1989).

However, reflections on the inadequacy of GNP, GDP, and GNI have led several scholars to develop a series of indices to overcome the limits of these monetary measurements and to systematically measure the costs and benefits of growth.

One of the first and most relevant alternative measurements is the Index of Sustainable Economic Welfare (ISEW). Developed by Daly and Cobb (1989), ISEW represents an alternative to GDP as it provides an integrated approach for

measuring economic development through the simultaneous use of different macroeconomic variables together with some social and environmental aspects. In other words, it is a sort of integrated index of economic development composed of a list of variables that seek to integrate traditional macroeconomic performance measures with some information on social, institutional, and environmental aspects. Specifically, ISEW can be calculated according to the following formula:

$$ISEW = C + G + I + W - D - E - N$$

where:

C is the personal consumption expenditure adjusted to the Gini index of income distribution (for income inequality).

G is public nondefensive expenditure.

I is the capital formation (and includes consumer durables, net capital growth, and changes in the net international investment position).

W is the nonmarket contribution to the welfare (services from domestic labor).

D is the private defensive expenditure.

E is the cost of environmental degradation (associated with habitat loss, localized pollution, depletion of nonrenewable resources, and climate change).

N is depreciation of natural capital.

ISEW is not the only sustainability index devised by scholars of this topic. Among the innumerable indicators, it is useful to highlight:

- Human Development Index (HDI) (UNDP 2005);
- Environmental Sustainability Index (ESI) (Esty et al. 2005).
- Environmental Performance Index (EPI) (Esty et al. 2006).
- Environmental Vulnerability Index (EVI) (SOPAC 2005);
- Well-Being Index (WI) (Prescott-Allen 2001);
- Living Planet Index (LPI) (WWF 1998);
- City Development Index (CDI) (UNCHS 2001).

Furthermore, Daly and Cobb's ISEW was originally calculated for the United States. Subsequently, it was applied to the economic systems of other countries, such as the United Kingdom, several Western and Northern European countries, Canada, Australia, and Chile. The application of this index to contexts other than the United States was conducted in various revisions of the calculation methodology on which ISEW was built. This led to the construction of further indexes, with slightly different methodologies: the Genuine Progress Indicator (GPI) (Cobb et al. 1995; Hamilton 1999; Redefining Progress 1999) and the Sustainable Net Benefit Index (SNBI) (Lawn and Sanders 1999; Lawn 2003).

All these indexes, of course, are not exempt from limits and criticalities. Some studies (Atkinson 1995; Neumayer 1999, 2000) have highlighted the limitations connected to the scarce theoretical basis supporting these methodologies, in addition to the weaknesses in the identification of the single variables of which these indices are composed.

Nevertheless, it is necessary to emphasize that the presence of limits and weaknesses cannot lead to denying the merit of these methodologies. In fact, beyond these physiological criticalities, they currently represent a concrete and very useful reference point for the definition of alternative indexes to GNP, GDP, GNI, and in general, to all those approaches that would lead to the adoption of all-inclusive judgments on performance of the economic systems of the various countries, from purely financial analysis processes.

Innovation and CSR

Maria Roszkowska-Menkes

School of Economics, Warsaw, Poland

Description

The strategic implications of corporate social responsibility (CSR) have become an important area of studies in business and society literature (see ▶ [“Strategic Management and CSR”](#)). The relationship between innovation and CSR is

among problems often tackled in this stream of research. As argued by Macgregor and Fontrodona (2008), these two elements are mutually reinforcing in a way they generate a virtuous circle. On the one hand, CSR, especially strategic CSR, is believed to drive innovation, as companies seek more socially responsible products and services, more environmentally friendly production processes, and new business models (Porter and Kramer 2011; Visser and Kymal 2014). CSR programs can result in radical process innovation, leading to substantial efficiency savings (Porter and Van der Linde 1995) or serve as a source of ideas and a test field for commercial projects (Kanter 1999). On the other hand, some firms that seek to enhance their innovativeness may design those processes in a more socially responsible fashion by, for instance, building relationships and cooperation with customers and suppliers (Macgregor and Fontrodona 2008).

Definition of Innovation

Although the literature provides various definitions of innovation, there is strong consensus among researchers concerning its main definitional attributes. “Innovation is a process of turning opportunity into new ideas and of putting these into widely used practice” (Tidd and Bessant 2018, p. 16). The definition stresses the process nature of the phenomena, setting a clear distinction between innovation and invention. While invention is the creation of new knowledge, innovation is its full development and exploitation. In other words, invention is the first step in the innovation process. The latter consists of four main phases: (1) search phase – seeking new ideas and opportunities to innovate; (2) selection phase – strategic choice (dictated by the organizational capabilities and potential competitive benefits) of the idea that the organization is going to invest in and develop further; (3) implementation phase – converting ideas into reality; and (4) capturing value phase – obtaining value (business or social) from the innovation process, protecting gains from appropriation by others, and learning from innovation (Tidd and Bessant 2018). Although

traditionally innovation has been viewed as a “specific tool of entrepreneurs” (Drucker 1985, p. 19) to build new businesses and achieve competitive advantage (Porter 1990), the value created in the innovation process can be also of a social nature (Murray et al. 2010).

Researchers distinguish between four basic types of innovation: (1) product/service – changes in the organization’s offering; (2) process – changes in production and delivery; (3) position – changes in the way users perceive a particular product or process; and (4) paradigm or business model – changes in the mental models about the way the organization creates value (Tidd and Bessant 2018).

Additionally, innovation can be of an incremental or radical nature (Henderson and Clark 1990). The first, focused on improving existing solutions, especially with respect to organizational processes, represents the majority of innovation in the market and often strengthen the dominance of market leaders. The latter induces Schumpeterian’s creative destruction (Schumpeter 1934) – they disrupt markets or create completely new ones, challenging existing players to adapt to the new rules of the game. The capacity to manage the innovation process and innovate (incrementally and/or radically) on a continuing basis is seen as a crucial factor of organizational success and survival (Brown and Eisenhardt 1998).

Definition of CSR

CSR refers to “social obligations and impacts of corporations in society” (Crane et al. 2008, p. 6). More specifically, the term can be defined as “international private business self-regulation” focused on minimizing social harms and contributing to social welfare by companies (Sheehy 2015). As the literature concerning CSR is strongly siloed, definitions of the term vary depending on the discipline (see ► “Definitions of CSR”). In the political sciences, the understanding of CSR has been centered on the idea that the firm is a corporate citizen administering civil, political, and social right in areas neglected

by governments (Matten et al. 2003). From an institutional perspective, CSR is viewed as an emerging international business norm. Finally, in economics and management studies, which are the most important perspectives for examining the link between CSR and innovation, the understanding of the term ranges from altruistic to strategic in nature. Within the first view, CSR is a profit sacrificing activity aimed at furthering social good, beyond the interests of the firm and legal compliance (McWilliams et al. 2006). Within the strategic approach, the understanding of CSR shifts from value redistribution toward value generation. Strategic CSR is seen as a voluntary business strategy aimed at the creation of shared value (Porter and Kramer 2011), i.e., gaining competitive advantage and generating social change at the same time.

CSR-Innovation Virtuous Circle

Macgregor and Fontrodona (2008) were among the first authors to explicitly discuss CSR in conjunction with innovation. They propose a conceptual model showing a two-way system of **CSR-driven innovation** and **innovation-driven CSR**. Since innovation and CSR reinforce each other, they form a virtuous circle. While CSR-driven innovation is driven by values and refers to the development of products or services that deliver social benefit, innovation-driven CSR is driven by economic value and is aligned with the creation of social processes. The authors explain that the former is about “doing the *right* things” and the latter is about “doing things *right*.”

CSR-Driven Innovation

According to Porter and Kramer (2011), targeting sustainability problems allows companies to manage the related risks and costs, as well as supports the identification of business opportunities. Other authors argue that socially responsible firms need to adopt innovation in order to develop radically new processes, products, services, and business models that could effectively address sustainability challenges (Blowfield et al. 2007).

Kozubek (2015) identifies four types of CSR-driven innovation: (1) corporate social innovation (CSI), (2) “base of the pyramid” innovation, (3) **eco-innovation**, and (4) social entrepreneurship. The first type, CSI refers to product, process, or business model innovation that addresses social and environmental problems and simultaneously generates business value (Kanter 1999). Firms can create new markets by addressing unmet social needs and use social programs as a test field for commercial products and process innovation. CSR projects can be carried out as innovations that challenge and improve the firm’s learning capabilities (Hull and Rothenberg 2008). The main idea behind the second type of CSR-driven innovation, i.e., innovation at the base/bottom of the pyramid (BOP), is to target the world’s population that has the least amount of income (London and Hart 2011) and that, due to the growing global economic inequality, do not have access to the global market. BOP represents a market full of underserved social needs and untapped opportunities for innovation (Blowfield et al. 2007) (see ► [“Base of the Pyramid”](#)). The third type of CSR-driven innovation is eco-innovation, which focuses on opportunities linked to innovative products and services addressing key environmental problems. It has been argued that eco-innovation can be successfully driven not by the demand of current users but by development of virgin markets (Kozubek 2015). Finally, the last type, “social entrepreneurship encompasses the activities and processes undertaken to discover, define, and exploit opportunities in order to enhance social wealth by creating new ventures or managing existing organizations in an innovative manner” (Zahra et al. 2009, p. 522).

Extensive theoretical research on CSR-driven innovation has been accompanied by few empirical investigations. Some studies show strong correlation between corporate social performance and research and development (R&D) intensity (used as a measure of innovativeness) (McWilliams and Siegel 2000; Lopez et al. 2008). This relationship is explained by the fact that firms with high level of CSR investment often pursue a differentiation strategy that requires complementary R&D investment (McWilliams

and Siegel 2000). Nonetheless, others provide empirical evidence that the association between CSR and innovation (again measured with the R&D intensity) is negative (Gallego-Alvarez et al. 2011) and argue that some CSR activities do not create value for companies and as such do not constitute a source of innovation.

It is strategic CSR (see ► [Strategic CSR](#)) that is believed to stimulate innovation in organizations (Kim and You 2013). Some authors argue that integration of sustainability-related goals with traditional business objectives requires radical innovation of processes, products, services, as well as business models (Visser and Kymal 2014). Continuous learning (Vilanova et al. 2008) and innovation (Osburg 2013) are seen as key to achieving strategic corporate responsibility. Companies with strategic approach to CSR innovate to build competitive advantage by reaching ethical and green consumers, enhancing supply chains, as well as expanding to BOP markets (Mirvis et al. 2016).

Innovation-Driven CSR

According to Macgregor and Fontrodona (2008) innovation-driven CSR is achieved through innovation processes where the end result may not necessarily have a social rationale, but the way the output is developed (e.g., through employee participation and collaboration with customers or suppliers) is more socially responsible. Additionally, empirical studies reveal positive association between R&D intensity and corporate social performance (Padgett and Galan 2010; Shen et al. 2016), which is explained by the fact that some R&D projects aimed at process efficiency might drive decrease in energy consumption and CO₂ emissions (Padgett and Galan 2010). Similarly, Husted and Allen (2007) in their study on corporate social strategy in multinational enterprises argue that firms can leverage their strong capabilities for innovation in other areas, including CSR. The authors show that there is significant relationship between firm’s innovativeness and its use of strategic social positioning. Another explanation for innovation-driven CSR, provided by Shen et al. (2016), is that CSR plays a significant role in reducing information asymmetry between innovative firms and stakeholders. To gain

legitimacy among stakeholders and secure their support for highly innovative and, in the same, highly risky venture, firms adopt CSR as a signal of their sustainability and goodwill. The relationship is stronger for firms with higher financial leverage and operating in markets with lower growth opportunities. Additionally, authors show that innovation serves as a moderator in a relationship between CSR and corporate financial performance.

Other studies present, however, contradictory findings. While Lopez et al. (2008) find no statistically significant relationship between CSR and R&D expenditure, Gallego-Alvarez et al. (2011) show that the relationship is negative. The latter is explained by the fact that companies that offer innovative products do not need CSR to attract customers (Hull and Rothenberg 2008).

Open Innovation and Strategic CSR (See ► Cooperation and Open Innovation)

Open innovation (OI) is defined “as a distributed innovation process based on purposively managed knowledge flows across organizational boundaries, using pecuniary and non-pecuniary mechanisms in line with the organization’s business models” (Chesbrough and Bogers 2014). It has been argued that “OI inherently corresponds with the strategic approach to CSR and that the concepts are mutually related” (Roszkowska-Menkes 2018, p. 959).

On the one hand, CSR-driven innovation addresses multifaceted social and environmental problems, as well as interests of various stakeholders. As such, it is more complex than traditional market-driven innovation and, thus, requires open approach to innovation processes (Blowfield et al. 2007; Osburg 2013). Such approach involves the use of nontraditional market information, close multistakeholder and intersectoral collaboration as well as complementary knowledge sharing. Chalmers (2011) argues that open paradigm can help companies in overcoming challenges for social innovation, including market protectionism, limited access to funding and to networks, risk aversion, and issue

complexity. OI processes support implementation of CSR strategies and integration of corporate social, environmental, and economic goals. Access to complementary resources and partnering with external stakeholders increase the chances for CSR-driven innovation to drive meaningful social change (Ayuso et al. 2011), and, simultaneously, boost firm’s competitive advantage.

On the other hand, as strategic CSR focuses on stakeholder engagement, it fosters creation of open, dialogue-, and trust-based organizational culture (Roszkowska-Menkes 2018). Such environment naturally promotes open approach to innovation. Strategic CSR stimulates stakeholder dialogue and collaboration (Greenwood 2007), fostering knowledge transfers (Luo and Du 2014). It also involves employee engagement (Bhattacharya et al. 2008) that has been proven to increase company’s absorptive capacity (Golightly et al. 2012), i.e., its ability to evaluate external knowledge, assimilate it, and utilize it (Cohen and Levinthal 1990).

Definition

The concept of innovation is synonymous with novelty, change, or renewal, being considered an essential factor for the economic development of an organization and the territory in which it is inserted. This means that innovation will be everything that allows an organization to achieve efficiency and effectiveness, reducing or eliminating surplus. This efficiency and effectiveness can be reflected in the provision of services, in productive, administrative, or financial systems. The Oslo Handbook (OECD/Eurostat 2005) defines innovation as the implementation of a product, well or service, new or significantly improved,

or a process, or a new marketing process, or a new organizational method in business practices, in the workplace organization and also in external relations.

For Oslo Manual (OECD/Eurostat 2018: 20), “an innovation is a new or improved product or process (or combination thereof) that differs significantly from the unit’s previous products or processes and that has been made available to potential users (product) or brought into use by the unit (process).”

The definition of innovation in last Oslo Manual (OECD/Eurostat 2018) condenses the four types of innovations (product, process, organizational, and marketing) to two main types, product innovations and business process innovation, and also reduces the ambiguity of the requirement for a “significant” change by comparing both new and improved innovations to the firm’s existing products or business processes.

Development is synonymous of progress and evolution, and innovation and territorial development can be understood as the inputs of the territorial innovation system, consisting of tangible and intangible assets, such as the human and intellectual capital, the social capital, the cultural capital, the natural and productive capital, and the institutional capital, that generate the productivity and development of the territory (Gallas et al. 2018).

Introduction

Increasingly, the concentrations of innovation foster success (Antunes 2011). In fact, the regions that are most endowed with innovative tangible and intangible assets are also those that occupy a better position in a hierarchy of territorial development, since they are able to capture more entrepreneurship and consequently generate greater synergies in knowledge and entrepreneurship (Oliveira and Natário 2009).

Innovation and territorial development studies seek to identify the role of different players (public authorities, research centers, universities, and companies, among others) and

analyze the articulations/networks that can be established among them in territorial development (Zambanini and Bresciani 2013). In fact, the combination of local or remote knowledge networks has profound implications for innovation and territorial development (Vale 2009). Other approaches are emphasized, such as the role of territorial assets and innovation in the development of creative cities, which are understood to be places that are capable of transforming themselves based on a deep understanding of their cultural identity (Gallas et al. 2018), or the role of social entrepreneurship, in particular the role of cooperatives, in territorial development (Oliveira and Natário 2009).

Key Issues

The particular focus on innovation as central factors behind economic growth and development is illustrated in national innovation systems of Lundvall (1992) and Edquist (1997). A system of innovation results from the interaction between the technological and scientific systems, since production results from creative knowledge and a process of feedback from the market and from technologies (Lundvall 1985; Antunes 2011).

The relationships between knowledge institutions and firms are also highlighted in triple helix approach where universities, government, and business are seen as the three important poles in a dynamic interaction (Etzkowitz and Leydesdorff 2000; Johnson et al. 2003). The focus is upon the systemic relationships between diverse actors territorially relevant with an important role in innovation process, generating dynamics of innovation (Natário 2005; Natário et al. 2006).

Edquist (1997) refers that innovation systems include all important economic, social, political, organizational, institutional, and other factors that influence the development, diffusion, and use of innovations. According to Johnson, Edquist and Lundvall (2003) innovation systems, competence building, and interactive learning are issues at the core of economic development.

When a company innovates, it seeks to obtain competitive advantages (preventive approach) in the sense that it seeks to impose higher standards for the service it provides or for the product it produces compared to its competitors. It can also innovate to not lose the position it already holds in the market in reaction to innovative competitors (reactive approach) (Antunes 2011).

In order to innovate, companies need to be able to transform knowledge into real innovation, but this transformation depends on the technological opportunities at their disposal (Antunes 2011).

According to the Lundvall (1992) and Edquist (1997), Innovation Systems approach and Higher Education Institutions (HEIs) have a determining role in the development of innovation and consequently in companies, in society, and in territorial development (Natário et al. 2013). In addition to teaching and knowledge transfer, HEIs also develop activities with a strong connection to the community in which they are inserted, as well as research activities in order to meet the needs of these communities. Etzkowitz et al. (2000) highlight a number of changes that have taken place over time, from a university centered on education to an entrepreneurial and research-centered university, thus contributing to the territorial development where they are inserted.

In addition to the HEIs, the interaction between the Government and the Companies, the so-called Triple Helix model, is also in line with the national systemic (Lundvall 1992; Edquist 1997) and regional innovation approaches (Cooke et al. 1997; Brackyk et al. 1998). The synchronization between these entities contributes unambiguously to the territorial development and sustainability of the regions, and once there is governmental support, companies and HEI manage to innovate and, on the other hand, to establish new audiences, thus generating an increase in income in the regions/places where they are inserted (Natário et al. 2013).

Future Directions

Future investigations may focus on the study of innovation and the development of creative

regions, i.e., how regions are able to transform themselves based on what they have of the most singular and creative, innovating and making known their potentialities to the people/regions that do not have or have little knowledge of their potential.

Summary

This chapter discusses the concepts of innovation and territorial development and the role of different players to promote innovation in a territorial context. The focus is on economic growth and development and is illustrated by territorial approaches to innovation, highlighting national innovation systems approaches and the triple helix model.

Synonyms

Business model; Circular business model; New business model; Sustainable business model

Definition

Innovative Business Models (IBMs) can be interpreted as an advanced, comprehensive, and transformed approach explaining how firms create value (O’Riordan 2017, p. 399). IBMs comprise many of the characteristics of both Business Models (BMs) and New Business Models (NBMs). (For clarification, while IBMs undoubtedly signify many of the concepts inherent in the BM and NBM logic, the semantics associated with the term “new,” which undoubtedly ages over time, designates “innovation” the more suitable label to depict the future value creation era.) Please refer to the explication of related concepts below for further details. Business model innovation derives from corporate practice, strategic management, and industrial economics (Carayannis et al. 2015; Teece 2010). Ćwiklicki and O’Riordan (2018) defined an IBM as the specification of a process for realizing a sustainable supply of relevant offerings that create value for clients, customers, the community, and/or other stakeholders. IBMs thus signify a form of sustainable BM based on an innovative stakeholder value creation logic. Via IBMs, value is generated by corporations in an inclusive way focused on collectively improving the well-being with and for multiple stakeholders in society (O’Riordan 2017, pp. 377–474). This topic is addressed in a separate entry written by the author in this Encyclopedia (see ► [“Stakeholder Value Creation”](#)).

Explication of Related Concepts

Business Models (BMs) are typically understood as a way of doing business which captures and delivers value (Saebi and Foss 2014, p. 204; Taran et al. 2015, p. 303). A review of the academic literature and mainstream management knowledge of BMs over the last 15 years highlights several definitions. Detailed analysis of its meaning conducted by Zott et al. (2011) indicates that no one unambiguous interpretation exists. BMs can generally be interpreted as a construct comprising both the rationale and the route for organizing value creation. BMs thereby depict the interrelated activities of planning, leading, structuring, and controlling as organizational processes (Jonker et al. 2015, p. 234).

By describing the organizational logic and the resulting processes from which value creation and delivery ensue, BMs provide insight into how an organization impacts different parties (Jonker et al. 2015, p. 234). By depicting how the company does business with its customers, partners, and vendors, among other stakeholders, the BM thus portrays the value proposition (Amit and Zott 2012, p. 42). The BM illustrates both the network of parties, as well as the different capabilities involved in creating, marketing, and delivering value (Osterwalder and Pigneur 2010). Conventionally, BMs focused on generating value primarily from an exclusive shareholder (supply side economic) perspective. This isolated economic emphasis focused on a competitive profit maximization route to value creation (Ćwiklicki and O’Riordan 2018).

New Business Models (NBMs) emerged as a response to various signals that the conventional exclusively profit maximization-focused value creation logic no longer functions. New ways of organizing were emerging in which the notion of sustainability was becoming more central. Highlighting the inclusion of multiple stakeholder interests and broader principles of value creation, NBMs signified a new generation of BMs. They directed the management focus beyond exclusive profit maximization by recognizing the strategic role of business in generating social and ecological value (Jonker and O’Riordan 2016, p. 543).

This accentuated the capability of the organization to create value both in and between organizations as organizing entities (Jonker 2012, p. 16). The development of this “new” generation of BMs signified a shift in the underlying values toward a value creation logic delivering mutual benefits via new types of relationships based on the practice of sharing, trading, and creating (Jonker and O’Riordan 2016).

Conceptual Foundation and Historical Development

Awareness of BMs essentially began in the mid-1990s with the advent of the Internet. A review of the increasing body of literature, which has subsequently emerged, reveals that the extant scholarship is primarily based on generic aspects of BMs largely related to themes including e-commerce, strategy, and innovation (Chesbrough and Rosenbloom 2002; Osterwalder et al. 2005; Shafer et al. 2005; Teece 2010; Zott et al. 2011).

While a study of the academic literature and mainstream management knowledge of BMs since their original emergence highlights several definitions, detailed analysis undertaken by Zott et al. (2011) on their meaning indicates no clear consensus on how BMs are interpreted. According to Lindgren and Jørgensen (2012, p. 6), BMs enhance innovation by presenting “a business operational manifestation of the way BM innovation works and is carried out from ideation to market introduction.” Afuah (2014, p. 4) defines BM innovation as “a framework or recipe for creating and capturing value by doing things differently” and indicates “change” as a main characteristic.

Originally, BMs focused on generating value primarily from an exclusive shareholder perspective. This isolated economic emphasis primarily on a competitive profit maximization route to shareholder value creation (Ćwiklicki and O’Riordan 2018). Magretta highlighted that single bottom line value creation logic when she expressed what she termed “. . . the fundamental question every manager must ask: How do we

make money in this business?” (Magretta 2002, p. 82). This emphasis on profit maximization was still evident 4 years later in scholarship relating to what could arguably be interpreted as the “next generation” of BMs, i.e., NBMs. Still in 2006, when writing about the value creation logic of NBM, many continued to overlook the negative impact of narrowly focused internal economic objectives on external social and ecological interests. For instance, Markides (2006, p. 20), stated at the time: “To qualify as an innovation, the NBM must enlarge the existing economic pie, either by attracting new customers into the market or by encouraging existing customers to consume more”.

Triggered by growing concern in the 1970s about the impact of corporate decisions on stakeholder groups, the United Nations (UN) World Commission on Environment and Development (WCED) developed the principles of Sustainable Development (i.e., proposing the processes needed to achieve sustainability). This culminated in the Brundtland Report (Brundtland 1987) emphasizing the underlying premise that economic activities designed to meet the needs of current generations are architected in ways which do not compromise the ability of future generations to meet their own needs. This highlighted the long-term aspiration that business activities would foster (and not harm) a synchronized global, peaceful, healthy, well-being for society when undertaking its commercial activities.

Advocating a management decision-making logic grounded in stakeholder theory, these principles encourage the connection of economic with social and environmental aims. These values were originally termed the “Triple Bottom Line” (TBL) principles. The TBL advocates a decision-making approach broadens the BM value creation objective beyond a single economic bottom line by advocating the need to take not one, but a triad of interests into regard. They include in addition to profits (development of a solid economic structure, which facilitates industrialization and reduces unemployment and social issues), people (elimination of poverty, facilitation of human health and education), and the planet (protecting

the environment). The rationale for broadening and synergizing this triple value creation logic is based on the assumption that sustainable harmony will result (Elkington 1997, p. 2) (see ► [“Triple Bottom Line”](#)). More recently, the TTL concept put forward by McDonough and Braungart (2002) proposed architecting multiple stakeholder interests into products and services already at their conception and design stage. Hence the term “Triple Top Line” (TTL) can be interpreted to reflect stakeholder regard directly from the outset in the top line (sales), as well as the bottom line (profits) (see ► [“Triple Bottom Line”](#)). These principles are generally understood as the fundamental source for sustainable business practice (see, for example, Jonker et al. 2011, p. 9).

One of the important features of BM innovation is highlighted as: “finding the optimal combinations of internal and external knowledge in ways that create and capture value” (Denicolai et al. 2014, p. 259). Some authors, including Jonker and O’Riordan (2016) and Ćwiklicki and O’Riordan (2018), have employed the label “New” BM in previous scholarship to signify a form of BM innovation. According to Ćwiklicki and O’Riordan (2018) however, overall, the academic definitions exhibited a lack of consistency in sufficiently describing BM innovation due to the different perspectives applied by the researchers (Spieth et al. 2014, p. 238).

In line with the increasing awareness for the need to shift toward sustainable development, a “new” generation of BMs arose from a crucially needed shift in the underlying mindset about how value is created. While this change was triggered by the realization that a value creation logic based on a broader regard for stakeholders rather than an exclusive shareholder perspective was required, the role of the market and economic mechanisms as the means for creating value nevertheless clearly remain key. Not only the TBL/TTL principles, but the very word “business” in the NBM term, as well as Carroll’s (1979) corporate responsibility definition (which includes an economic, as well as legal and ethical responsibility of business), clearly highlight the essential role of profits in all forms of BM value creation. Despite these

definitions, as concepts of NBMs evolved over time, the role of economic outcomes as the essential consequence of business was initially diminished by some scholars. For instance, the scholarship presented by Dentchev et al. (2016) and Teece (2010), among others, could be interpreted to imply that profit generation stood in conflict with the NBM value creation logic.

Today, instead of criticizing business for causing social and environmental problems, protagonists, such as Harvard Business School Professor Michael Porter, renowned for his theories on economics and business strategy, reasons that precisely because business makes profits by solving problems, it can play a powerful role in solving the social and ecological challenges facing mankind. Moreover, Porter advocates that of all the possible stakeholders who could shape change, business can do this best simply because it has the greater resources (Porter 2013). Consequently, a prerequisite for distributing wealth is that it is first generated. Delivering economic value based on their strategic choices not only ensures the organization’s long-term survival. Harnessed fairly and aligned with social and ecological interests, business can help to concurrently address a broad range of multiple stakeholder interests. Profits remain, therefore, in addition to their other areas of accountability, an essential responsibility of every business decision-maker. Based on this rationale, sustainable NBMs do not contradict conventional BMs per se, but simply represent a broader scope of value creation logic. Profits thus remain key as long as they are not achieved at the expense of other stakeholder interests.

In contrast with the short-term, profit-maximizing wealth-generation focus of narrower shareholder value creation strategies, corporate decision-makers are increasingly beginning to embrace the rationale of stakeholder theory when making management choices. For clarification, the term IBM is employed by the author to avoid the semantic issues associated with the term “new” in NBMs. Based on the rationale that there is nothing as old as a new idea, the term “innovation” was purposefully chosen as a more appropriate label to depict the qualities of BMs in the

future value creation era. Clearly, however, IBMs undoubtedly signify many of the concepts inherent in the BM and NBM logic. Arising from the realization that an over-emphasis on shareholder dominance is harmful to society and the environment (Hampden-Turner et al. 2019, pp. 28–37), contemporary concepts of IBMs build on sustainable TBL/TTL principles by encouraging the organization of business activities to optimize the achievement of *mutual benefits* in stakeholder relationships. The inherent innovation in IBMs is generally defined by Casadesus-Masanell and Zhu (2013, p. 464) as the search for new logics of the firm, new ways to create and capture value for its stakeholders, and focusing, primarily, on finding new ways to generate revenues and to define value propositions for customers, suppliers, and other partners. Essentially, this new value creation logic is focused on reciprocal/circular benefit in relationships. For instance, the role of money as the primary rationale and “currency” in trade underwent reassessment. This reflection led beyond money as the sole basis for exchanges to a broader mix of additional (hybrid) values. Further possibilities such as nature, time, care, silence, attention, and energy, among others, became salient. In the evolving NBM logic, for example, attention on *access* to the means of production became more important than their ownership. Likewise, *using* became more salient than controlling the key factors and resources of production. Thus, the NBM notion paved the way for a cooperative value creation approach centered on long-term commitment between stakeholders (O’Riordan and Zmuda 2015, p. 234).

Resulting from these developments we can summarize that sustainable NBMs, which could be interpreted as an early form of IBM, do not stand in contrast with conventional BMs per se, but simply represent an ever-broadening and deepening scope and quality of value creation. Their inherent value creation logic, driven by sustainable, TBL/TTL, stakeholder-orientated values, signifies a shift in leadership awareness and mindset toward the voluntary integration of social and environmental interests into the business purpose. The strategic business activities of planning, investing, and organizing resources

along the entire value chain of the business thereby recognizes social and ecological needs as valuable business opportunities. This interpretation of sustainable IBMs assumes a broad enabling scope for business. It envisions companies, as well as other parties and intermediaries, as catalysts for facilitating market-mediated access for and between customers/users to business solutions. The goal of business success thereby becomes a motor for social and environmental solutions driven by economic exchange mechanisms. Ultimately, business becomes strategically connected with society.

This transformation signifies a quest for BM innovation beyond the earlier conventional profit maximization focus. The resulting IBM value proposition advocates a broader stakeholder value optimization approach. It can arguably be interpreted to include interrelated principles of value creation enabling collaborative business strategies serving to promote novelty, inclusivity, and general well-being for all stakeholder constituents. Its inherent broadened scope can be interpreted to derive from several premises based on the general aim to ground management decision-making on stakeholder theory and hence create value based on a stakeholder value creation logic. The emerging but compelling discussions, which challenge the way capitalism is currently organized, will continue to raise questions about how long-term stakeholder value is optimally created (Hampden-Turner et al. 2019).

Wealth Creation: Wicked Problems Call for Wicked Solutions

Abundant evidence suggests that great progress has been achieved over the past two centuries in improving worldwide prosperity. On many measures people today are wealthier, healthier, better educated, live in safer and cleaner environments, are better nourished, and entertained than in the past (Bregman 2016). One key catalyst for this progress has been the cumulative effect of individual corporations generating great wealth via their conventional BM logic. However, a

fundamental dilemma of our time is that this “progress” has come at a high price. While the linear model of an economy defined by three words “take, make, throw” in theory assumes access to infinite resources and energy, in practice, those resources are diminishing. Mankind continues to face many “wicked” problems, including among others: nutrition and access to water issues, deforestation, lack of food and skills, insecurity, insufficient health care, and pollution (O’Riordan and Hampden-Turner 2021). Addressing these problems requires improving the level of recovery and recyclability of waste (Braungart and McDonough 2009). Counteracting the cumulative negative effects of, for instance, an exponentially rising global population, increasing consumerism, and unsustainable market mechanisms, sparks the general need for innovative solutions to improve our capability to sustain mankind’s needs within the systems that we have constructed. The main issue, however, is that neither the politics nor the economic system needed to fix the existential wicked problems of our time exist today. They need to be created.

Addressing this issue is one of the key contemporary social challenges (Chomsky 2017). International experts in the field including the world-renowned leader in environmental stewardship, David Attenborough advise that the climate change crisis is “difficult to overstate” (Attenborough 2019). Environmental change is happening ever faster and threatens to destabilize society. If the world fails to act, researchers warn of significant and dangerous changes including disruptions arising as the consequences of rising sea levels and significant changes to ocean temperatures and acidity continue to amplify. For instance, the ability to grow crops such as rice, maize, and wheat, among others, would increase problems with food and water supplies. A report released by the leading international body evaluating climate change (IPPC 2018) warns that such effects could potentially trigger price spikes driving civil unrest, while increases in levels of migration would strain societies. Combined, these factors could overload political institutions and global networks of trade (O’Riordan and Hampden Turner 2021).

Many continue to believe that business is responsible for causing the above-noted problems. This accusation might well appear justified considering the ongoing business scandals continually gripping the media headlines. While business has undoubtedly earned a negative image due to the leadership choices of various decision-makers from numerous sectors, including oil, banking, pharmaceuticals, tobacco, and fast food industries, among others, crucially, the evidence suggests that only business wields the degree of power (via its resources) required to achieve positive impact.

The efforts undertaken to date to address the environmental and social challenges facing mankind have not been satisfactory. Although the still-evolving concepts of NBMS and IBMs as a construct comprising both the rationale and the route for organizing value creation have recently begun to gain traction, realizing their inclusive, sustainable, stakeholder-orientated value creation output via the interrelated activities of planning, leading, structuring, and controlling as organizational processes requires a crucial shift away from the traditional narrow shareholder-focused leadership mindset. Because an isolated economic emphasis on a competitive profit maximization route to value creation ignores the external impact of the organization on the various affected parties, a new and innovative organizational logic as a basis for redesigning business processes from which value creation and fair delivery ensue is urgently needed (Ćwiklicki and O’Riordan 2018). The inherent value-generating logic of IBMs suggests that they may potentially hold many of the characteristics required to address the above-noted issues.

Future Directions

The above-noted issues trigger the need for enormous change. The increasing support for Greta Thunberg’s Fridays for Future movement is one powerful indication of the increasing awareness in society that we cannot solve problems by using the same kind of thinking we used when we created them. Innovative solutions are needed. But novel routes require a “leap of faith.” Rather than

automatically repeating the same habits from the past, or replicating the actions of others, differentiation demands a route via the path less traveled. Unique opportunities arise on this path if ingenuity, resourcefulness, and insight are enabled to flow. But the first step is a willingness to change. The quote from the physicist Albert Einstein “Any fool can make things bigger, more complex, and more violent. It takes a touch of genius – and a lot of courage – to move in the opposite direction,” is still highly relevant in business world today.

As the business world grapples with the rising concerns of society, management decision-makers can rise to the challenge by investing their resources sustainably. When transforming resources, including land, labor, capital, and enterprise into outputs, the leaders of organizations make choices based on value judgments, which impact its stakeholders (see ► [“Stakeholder Relationship Management”](#)). Because BMs serve the purpose of describing the design or architecture of the value creation, delivery, and capture mechanisms employed by leaders to realize some chosen purpose, they serve as an important vehicle for change. The next generation of BMs could serve the people it impacts by creating first social and environmental, then, as a result, economic value.

By realizing profits as a consequence of the stakeholder relationships it enacts, business evolves as a means through which people serve (not exploit) other people. Leaders in organizations can make conscious choices to harness the resources they invest. Driven by the sustainable values inherent in a transformed stakeholder-orientated purpose, BMs evolve to transform organizations into catalysts for enhancing value creation in society. Innovative solutions via fruitful stakeholder relationships ensure sustainable business responses.

To achieve this human-centric business model, a transformation in the current management attitude and an advanced BM construct is required. A key prerequisite for sustainable development is the premise that the actors in the stakeholder network from both public and the private sector must in the first instance adopt a leadership mindset, which better serves society. This innovative

perspective generates intrinsic opportunities with broadened leverage for those organizations in which decision-makers choose to contribute not merely to the economic, but also to the social and environmental needs of society (e.g., Roddick 2000, p. 14).

Applied at the macro-level, this requires transitioning toward public sector frameworks in which political, social, and economic, as well as other pertinent systems better serve society (O’Riordan and Hampden-Turner 2021). However, precisely because Government, non-governmental organizations (NGOs) and other individuals or groups have not satisfactorily addressed the pressing problems of our time, solutions need to be initiated elsewhere. In the private sector, commerce must serve society and not the other way around! What is needed is a mindset reset among management decision-makers to trigger awareness of the potential to create long-term sustainable profits by investing internal and external resources to solve societal needs. Business makes profits by selling its offerings at a price, which generates sales revenue. Costs are subtracted and profits ensue. The stakeholder relationships in this process require reconsideration. While business typically contributes to society by paying taxes and income to employees, as well as via social subsidies and charitable donations, the external costs of its activities must be included in the overall assessment of its contribution to society. Systems for transparent accountability must improve and measurement instruments must be developed to capture the inclusive stakeholder value that is created. Those who argue that business *causes* problems must, based on the same rationale, recognize the enormous potential held by business to serve as a catalyst in unleashing the momentum needed to *solve* societal issues.

Realizing its full capabilities will require a fundamental change in the current value creation logic of organizations. From a management perspective, the overly prolonged belief that a short-term shareholder focus is a reasonable way to invest collective resources is misled. In the long-term, business *does not* logically profit in any essential way from causing pollution, resource depletion, social problems, or any of the other

negative (tragedy of the commons) impacts for which it is frequently held accountable. Instead, creating sustainable value (prosperity, wealth, and well-being) requires recognition of collective equity among stakeholder groups as well as generations, according to the UN Brundtland Report (Brundtland 1987). The single-minded emphasis on profits for the holders of equity overlooks those who do the actual work and must master the skills needed in the years to come. More money is extracted in the short-term than invested in the long-term (O’Riordan and Hampden-Turner 2021). Freeman (1984, 2018) shows that wealth is created by a broad alliance of stakeholders whose rewards must be commensurate to their contributions. A triple bottom line (TBL) and top line (TTL) approach is needed (Elkington 1997; McDonough and Braungart 2002). Profits are the consequence of shared efforts not the purpose of them (Grant 2006, p. 41).

Of all the possible alternative stakeholder groups, only business possesses the resources to affect the adequate large-scale impact required to address the wicked and increasingly intensifying problems facing mankind (e.g., Porter 2013). Mobilizing the means to address these issues will however require a fundamental shift in the management mindset regarding how business creates value. This will necessitate intensified reconsideration of the role of profits in creating value in society. In pursuit of the scale and scope of solutions required to address the issues facing society, a mindset reset is required by all stakeholders. New insights are needed for architecting novel value propositions of the way in which organizations engage in business with its customers, partners, and vendors, as well as other interest groups.

In line with the interpretation of the original Latin meaning of the word “competition” (i.e., “competere”), in a stakeholder value creation approach, competitors strive *together* in synergy to achieve connected objectives thereby realizing synergic value (O’Riordan 2017, pp. 3, 387–388 and 423–424). Based on Aristotle’s rationale, politics, economics, and ethics comprise the key pillars of engagement, and the overall value outcome is better than the sum of its parts (Aristotle’s 1993 and 2001). Converting to the values inherent in

this stakeholder-orientated sustainable development approach essentially requires the fundamental connection of allied interest groups collaboratively realizing progress together resulting in the effective harmonization of multiple goals (e.g., O’Riordan 2017, p. 393). In this way, co-ordinated TBL/TTL outcomes are achieved including: Profits via the development economic structures, which facilitate sustainable development and generate employment; People through improving health and education while eliminating poverty; and Planet via environmental protection.

In her book on conceptualizing stakeholder relationship management, O’Riordan’s stakeholder value creation framework proposes a corporate approach for measurable stakeholder relationship management (O’Riordan 2017, p. 380). The framework depicts four steps to value creation depicting the transition from a conventional BM to an IBM. It is founded on an empowerment mindset in which humanity is integrated into the organizational strategy. This innovative value creation logic shifts the organizational logic from a network of stakeholder relationships in which power is wielded *over* people, resulting in powerlessness, to one in which power is achieved *through* people, i.e., empowerment. Corporate Responsibility (CR) thus becomes the cornerstone of the company’s purpose for being and accordingly drives its strategy. From this perspective of corporate mission, effective CR strategies are realized via novel forms of leadership engagement (see ► “Corporate Responsibility”). This new awareness signifies a deepening and broadening of the concept of “business” in which people focus on doing things for people as the definition of “business rationale.” Sustainable profits thereby flow from commercial activities, which serve to improve the overall well-being of society.

IBMs offer an exciting framework for achieving the necessary value creation logic transition. However, effective strategies clearly require a new form of leadership awareness, connection, and realization of value creation in synergy and harmony with the natural and social environment. The rationale for this transition is driven by

stakeholder-orientated purpose (Freeman 2018; O’Riordan 2017) (see ► “Stakeholder Theory”).

These insights indicate that future developments will require fundamental change in the relationship between business and other stakeholders in society today. Based on the objective to seek to create mutual value by connecting all the entities that are impacted by the decisions of the organization, BMs must evolve to nurture stakeholder interests. To intrinsically enhance the capitalist system, new strategies, measurement methods, and criteria are required to achieve this shift. As a crucial prerequisite for this transition, a circular value creation flow must replace the current linear approach. This requires a transition to a Circular Business Model (CBM).

CBMs connect all levels of the business from the external macro- and micro-level influencing factors to the organization’s internal resources. They serve as a useful organizational construct for achieving sustainable solutions, which enable more optimally balanced TTL/TBL value for a broader range of constituents than “conventional” BMs. This implies that the classical stakeholder spoke-and-wheel thinking is replaced by a much wider networked scope of parties involved in creating value, such as citizens, NGOs, and others besides business or governments. CBMs could be construed as a natural outgrowth of conventional BMs and a logical development of NBMs and IBMs. They will however only flourish if the external conditions in the broader system are favorable. This includes the development of a circular economy, which is evolving from novel advancements, such as: Cradle to Cradle, Reverse Innovation, the Collaborative/Sharing/Access economy among others influences. Based on Schumpeter’s rationale, by “democratising wealth,” such solutions enable sustainable business with respect to the use and distribution of, as well as access to scarce resources for customers (Schumpeter 2008). As one example of an inclusive, multi-stakeholder, up-cycling economy, a Circular Economy operates on the underlying idea of constructing a system in which social and ecological value are sustainably designed based on biomimicry. This is achieved by developing an offering (product or service for top line sales)

within a system, which is restorative and regenerative by design. This intrinsically enables sustainable processes that are comprehensively conceived from conception, through sourcing, to manufacture, use, and discard (preferably into new raw materials).

Recognizing the decision-making process inherent in CBM transition relates to the wider theme of decision-making in multifaceted scenarios. CBMs offer the possibility to revise the current value creation approach by connecting the business logic with the well-being of society. However, because managerial decision-making in the complex conditions represented by this transition is to date under-researched (Ćwiklicki and O’Riordan 2018), further academic work on the transformation from a conventional to a CBM is required. Future research could focus on the circular “flow” inherent in CBMs. Circularity is a means for synchronizing value creation via the architecture of permeable, reciprocal “constructs” between the parties. In this future scenario, the management decision-maker can be equated with the role of a conductor directing (or shaping the output of) an orchestra. All the “instruments” (stakeholder parties) are aligned in tune (values) to resonate in harmony via a music script (purpose) from which the collective expression of “music” ensues. The “rebound” or “echo effect” ensures an optimal “melody” value creation by and for all parties in the “network” including the “audience.” **Thus the underlying business purpose evolves** from the aim to survive **to the ambition to create**. In this process, realizing the benefits of circularity facilitates a transition from a primal competitive focus on survival to collaborative value creation delivering reflected, respectful, purposeful stakeholder solutions.

Summary

IBMs comprise a shift in the design of the conventional wealth creating logic of how organizations transform resource inputs (land, labor, capital, enterprise) into outputs (products and services). They present a transition from the traditional linear approach by manifesting stakeholder

value creation values into tangible business processes. The entrepreneurial purpose of decision-makers architecting an IBM approach drives the conscious, inclusive, and sustainable creation of optimum positive impact for all those interest groups who can affect or be affected by the business process. The value generated by corporations (outputs) designing IBMs thereby inclusively creates collective well-being with and for multiple stakeholders in society. This approach shifts the business processes toward a circular economy value creation logic delivering mutual benefits via new types of relationships within and between the constituents of the entire operating environment. The inherent optimal creation of economic value as a consequence of effective stakeholder relationships thereby concurrently and inclusively ensures the fulfillment of commercially crucial shareholder interests. Ultimately, IBMs signify a novel mechanism for decision-makers to transition via their business processes toward implementing sustainable business strategies in society. This not only innovatively but also comprehensively (holistically) connects the interests of all stakeholders in the interest of collectively achieving optimal outcomes. Ultimately, via the innovatively architected circular system, societal well-being is consciously enhanced. The process is still evolving, and further research will help to explain the necessary enablers and barriers, as well as the practices and policies required to achieve IBM stakeholder value transition.

Insider Trading

Nirmala Lee
 Guildhall School of Business & Law, London
 Metropolitan University, London, UK

Synonyms

Insider dealing; **Market rigging**; Conspiracy to defraud by using privately available information that is not yet in the public domain.

Definition

The term “inside” is derived from ynneside initially meaning in the late fourteenth century interior part of the body and from c. 1500 of anything. The adjective sense “being on the inside” is from 1610s, from the noun. It began to be used in slang c. 1900 to refer to the supposed real facts or situation that only an insider would know. The meaning of “one in possession of special information by virtue of being within some organisation” is said to date from 1848 and to have originated with particular reference to the stock markets. Trade in the sense of “buying and selling, exchange of commodities” dates from 1550s (see <https://www.etymonline.com/search?q=trade> on Online Etymology Dictionary, accessed August 9, 2020). Insider trading can be legal or illegal depending on whether the insider is trading using information that is available in the public domain.

Illegal insider trading and insider dealing refer to the unacceptable practice of trading in stocks to obtain an unfair advantage through gaining “inside” information that is not available to the “outside” public.

Introduction

Insiders who make use of their inside knowledge to profit from it are described as “opportunistic insiders” who seek to make “abnormal returns” from trades and market manipulation (Biggerstaff et al. (2020, 1); such insiders have been often found to report their transactions after close of business trading hours in order to preserve their informational advantages. “Insiders” could include CEOs, directors, major shareholders, and managers of companies as well as anyone who receives a tip off about a future event or development that may have an impact on prices of stocks and shares; television stars, entrepreneurs, agents, analysts journalists, professional golfers, spouses, relatives, and friends are reported as having been charged with and/or convicted of insider trading. As pointed out by Liu et al. (2020, 1), the “detrimental effects” of insider trading is well known and has been well researched and recorded. Insider trading provides an unfair advantage to “insiders” who are in the know and make use of their inside knowledge to generate profits for themselves at the expense of those who are outside and not in the know. The practice leads lack of transparency and opacity in financial markets and could result in discouraging ordinary investors from participating in what they might perceive to be “rigged” markets.

Insider trading is illegal in the UK from 1980 (Barnes 2011). However, the practice is viewed as being widely prevalent and is difficult to prove. While there have been some recent high-profile convictions, such convictions have been few in comparison with the perceived scale of its occurrence, and researchers are looking to see if other variables such as corporate social responsibility can mitigate its occurrence and impact.

Martineau and de Vanssay (2019, 1) distinguish between three different trading behaviors: (1) “Active insider trading behaviour” describes behavior resulting in the modification of a stock portfolio reallocation decision on account of inside information received about stock that is not in the public domain. (2) “Passive insider trading” describes behavior resulting in the cancellation of a stock portfolio reallocation decision on account of inside information received about stock that is not in the public domain. (3) “Pure ethical trading behaviour” describes behavior that does not result in any change to a stock portfolio reallocation decision despite non-public information received about the stock. The study concludes that pure ethical trading alone is not likely to effectively discourage the illegal practice of insider trading.

Insider Trading and Corporate Social Responsibility

Corporate social responsibility (CSR) builds a positive image of caring for social good for a firm, whereas insider trading is perceived as self-serving and builds a negative image. There is some research to show that executives of CSR-conscious firms are less likely to engage in insider trading (Klein and Leffler 1981; Gao et al. 2014). Other research finds that CSR may actually mitigate losses from insider trading, leading to a positive correlation between the two (Godfrey et al. 2009; Minor and Morgan 2012). However, in cases where executives’ personal interests are more aligned with the interests of the firm, the negative association between CSR and insider trading profits is more pronounced (Gao et al. 2014). Kim et al. (2014) similarly find that firms that actively engage in CSR also refrain from bad news hoarding behavior, thus reducing stock price crash risk.

A firm’s investment in corporate social responsibility (CSR) builds a positive image of caring for social good and is said to impose additional costs on executives’ informed trading, which is widely perceived self-serving. There is some research to show that executives of CSR-conscious firms are

more likely to refrain from informed trading and profit considerably less from insider trades and are less likely to trade prior to future news than executives of non-CSR-conscious firms. The negative association between CSR and insider trading profits is more pronounced when executives’ personal interests are more aligned with the interests of the firm. Thus, alignment of interests appears to be an effective approach to countering insider trading.

Insider Trading and Sustainability

Social sustainability has been found not only to play an important role in enabling other sustainability initiatives but also to facilitate business success. Unfair and unethical practices, such as insider trading, can negatively affect trading partners (Mani et al. 2016). Economic, environmental, and social aspects of sustainability have been found to extend beyond organizational boundaries, flagging up the importance of managing sustainability initiatives. The increasing emphases on sustainable business practices and corporate social responsibility in recent times are witness to the recognition of this importance.

Investor confidence plays a key role in the long-term survival of a company. Knowledge that insider trading is going on in a company is bound to deter investors, and conversely sustainability practices in certain areas have been found to be rewarded by investors (de Lange 2017).

Summary/Conclusion

Insider trading has implications for sustainability. It is crucial that dealings in the stock market and elsewhere are transparent and open not only on account of sustainability and ethical issues but also for preserving the long-term health of market-based systems. Firms would need to recognize that in the long term, profits and business success are linked to sustainability and ethical trading practices.

Introduction

The Institute of Chartered Secretaries & Administrators also known as The Governance Institute was established in 1891 in Great Britain. It was granted the Royal Charter in 1902. The Institute is the premier global qualifying organization for individuals aspiring to become chartered secretaries and/or chartered governance professionals. Its members have roles in industry and commerce as company secretaries, governance advisers, risk managers, compliance managers, in academia, and many

more. Since 1891, the Institute has successfully transformed itself into a global body of professionals in senior management roles in both public and private sector organizations. Its members' broad skill set includes law, finance, governance, strategy development, risk management, and compliance. It has about 40,000 members with several thousands of students in more than 80 countries worldwide. It has country-based offices in nearly all the 80 countries. Its head office is based in London, UK. Many of the old UK colonies which are members of the Commonwealth of Nations have their largely autonomous affiliated ICSA offices, in countries such as Australia, Botswana, Canada, Hong Kong, India, Kenya, Malawi, Malaysia, Mauritius, New Zealand, Nigeria, Singapore, South Africa, Sri Lanka, Tanzania, Zambia, Zimbabwe, and many others.

The ICSA in the UK, states that "it promotes best practice in corporate governance, liaising with governments and regulatory bodies worldwide." The corporate secretary is a senior corporate officer who is expected to hold wide ranging responsibilities and is often the confidant and counsellor to the Chief Executive Officer and other members of senior management, especially on corporate governance affairs. The Institute of Chartered Secretaries and Administrators in both the UK and in some of the country's other former colonies mentioned earlier, for instance, Australia, Canada, New Zealand, and others consider that governance is one of the main duties of corporate secretaries.

In the UK, the Institute of Chartered Secretaries and Administrators (ICSA) is the professional body which assesses and certifies the competences of prospective chartered secretaries or chartered governance professionals with a series of examinations and post qualification (CPD) programs. The ICSA is the only body among the seven chartered bodies mentioned in the Companies Act 2006 and specified in section 273 subsection 3a – 3g CA 2006 which trains its members solely to become corporate secretaries and governance professionals. Having said this, it must be noted that qualified members of the ICSA do end up in other senior

executive positions in organizations which are not necessarily in company secretariat. The ICSA is one of the 11 professional bodies in the UK whose members are authorized by the Charities Act 2011 to conduct independent examination of charities whose gross income exceeds £250,000 but not subject to the statutory audit. There are three grades of membership of the Institute – GradICSA membership those who have successfully completed the required qualifying examinations of the Institute; Associate membership (a member becomes an Associate (having completed the Institute's examinations, goes on to gain the necessary practical experience, and deemed of appropriate upstanding character); and Fellow membership (an Associate becomes a Fellow after a period of time in a senior management position in their chosen industry). The Institute represents the chartered governance profession with all external bodies including governments and international organizations. It also embraces the needs of professionals in other sectors, such as health, sport, education, and charities that regularly face new regulation that requires them to keep up to date in their field.

Brief History

The Institute was established in 1891 to represent the interests of the then emerging profession of corporation secretaries. It was granted and became a Chartered professional body in 1902. The Institute's purpose of leading effective and efficient governance and administration of commerce, industry, and public affairs continues to guide its activities even well into the twenty-first century.

Mission/Guiding Values

The mission of the Institute is to champion good governance and develop the value, skills, and effectiveness of company secretaries and governance professionals.

The following are the Institute's stated guiding values:

Openness – It champions transparency and requires its members to be clear and open in their business and professional conduct.

Integrity – The Institute works in the public interest and consequently believes that being honest and having strong moral principles is at the heart of good governance. The Institute acts ethically and professionally and requires its members to be ethical, professional, impartial, independent, and informed.

Authority – The Institute being a leading authority in governance matters takes its role in the regard seriously and demands a high standard of professional competence from its employees and members throughout their working lives.

Defining Institutional Investors in the Financial Market Ecosystem

In numerous publications, different definitions of institutional investors are used (e.g., Davis & Steil, 2001; De La Cruz et al., 2019; Matos, 2020). Some of them present a narrow view, while others offer a wider perspective. This entry will introduce a definition based on the functions performed on financial markets (see Fig. 1). Financial markets are basically defined by the exchange of funds between lenders (L) and borrowers (B) in a given institutional framework (Strumeyer & Swamy, 2017). The resulting financial contracts are characterized by a delay between the payment made by the financiers and the future return made by the borrowers. Accordingly, these contracts on financial markets differ seriously from other exchange contracts resulting from spot transactions and future contracts. In addition to the so-defined primary financial markets, unfulfilled financial contracts can be traded on secondary markets.

Financial contracts are typically concluded between the original partners (see Fig. 1, top). However, due to the signature gap between performance and consideration, financial intermediaries (FI) evolved on real financial markets over time dealing with frictions that occur on financial markets: information problems, term problems, denomination problems, and risk problems. There are two types of financial intermediaries: financial intermediaries in the narrow and in the broader sense. Financial intermediaries in the narrow sense (n.s.) become an additional contract partner between the two original partners. Accordingly, the original financial contract is split into two contrary contracts (see Fig. 1, bottom). For example, banks emerged originally as a financial intermediary to transform quantities and terms of funding. Rather than becoming a reverse contract partner between the original parties, the second type of financial intermediaries in the broader sense (b.s.) performs a service function to the conclusion of the original financial contract (see Fig. 1, top). For example, rating agencies support the conclusion of debt contracts, and

Institutional Investors, Fig. 1 Financial market ecosystem. (Source: own figure)

stock exchanges set the framework for secondary financial markets.

The existence of financial intermediaries on real financial markets is analyzed and explained in different theoretical frameworks (e.g., Boehmer & Kelley, 2009). For the explanation of functions performed by financial intermediaries, the broad literature refers to imperfections introduced in the basic neoclassical model of perfectly competitive financial markets: asymmetric information, transactions costs, and risks (e.g., Simpson, 2014). A taxonomy of financial intermediaries can refer to these typical functions performed on financial markets. Although grouped together in many research papers, institutional investors make up a diverse group (MSCI and OECD (ed.), 2018). Institutional investors in this entry are defined as financial intermediaries in the n.s. becoming the middleman between the original contract partner and other financial intermediaries by reducing market imperfections (see Fig. 2). Accordingly, institutional investors can become shareholders by investing in equity contracts, or they become creditors by investing in debt contracts.

When it comes to equity investments, institutional investors are supposed to be the more active

type of owners in comparison to private investors (Johnson et al., 2010). Accordingly, one part of literature focuses on the control functions performed by institutional investors (Jensen & Meckling, 1976; Shleifer & Vishny, 1986). On real financial markets, institutional investors are consistently monitored by policy makers, and over time, a vast set of regulations has been developed around the world. While bank and insurance regulation have a long history, rules for investment, pension, and government retirement funds developed over the last decades due to the increasing role of these intermediaries on financial markets in general and the supposed responsibility in (financial) crises (e.g., Shleifer & Vishny, 2011; Glossner et al., 2021). In many countries, institutional investors are regulated through different instruments, e.g., limiting the investment decision, the funding behavior, or the legal forms.

Institutional Investors, Ownership, and Sustainable Development

Currently, the ownership power of institutional investors is in the limelight of different political

Financial Intermediaries	Typical Examples		Main Functions

initiatives, especially the United Nations (UN) “2030 Agenda for Sustainable Development” and the 17 Sustainable Development Goals (SDGs). There are merely two major reasons for focusing on institutional owners. First, these specialists are supposed to have major impact on the future sustainable development due to the high and increasing volume of managed funds (Matos, 2020). Institutional investors are the majority of shareholders of publicly traded companies in many regions around the world (see Fig. 3). The importance of institutional

investors is the highest in the United States (72%), followed by other advanced countries (39%) and Europe (38%), whereas institutional investors (9%) are clearly dominated by public sector investments in China. This tremendous rise of institutional investors has been driven by investor’s recognition of the value of low-cost diversification (risk transformation) and was encouraged by favorable regulatory and tax treatment.

Second, institutional investors are in the center of sustainable development since corporate

governance was basically improved by the increase in this type of investors. With equity contracts concentrated in the hands of specialists, corporate managers face powerful shareholders to engage with (McNulty & Nordberg, 2016; Dimson et al., 2015): In contrast to atomistic and powerless private investors, institutional investors frequently show a high engagement or even activism in equity markets. By turning institutional investors into societal stewards, the traditional performance-oriented perspective of financiers can be extended by societal aspects (Serafeim, 2018; Staub-Bisang, 2012). Competition on financial markets will guarantee that access to financial resources is only available to companies which transform their business models in line with the SDGs (Di Giuli & Kostovetsky, 2014; Cheng et al., 2011; Petersen & Vredenburg, 2009; Ferreira & Matos, 2008).

Following this function in corporate governance, the UN started a project with institutional investors to accelerate the development of a fitting sustainable global financial system. The discussions ended in the launch of the six Principles for Responsible Investment (PRI) in the year 2006. This voluntary set of investment principles offers guidance to possible actions for incorporating Environmental, Social, and Governance (ESG) factors into investment practice. The number of signatories on the PRI increased rapidly over the decades (PRI (ed.), 2021). Additionally, the more general goal of promoting shareholder engagement with their investee companies was pursued by many politicians (Klettner, 2021) and led to other initiatives, best practice guidelines (Boffo & Patalano, 2020), and some national codes (e.g., the UK stewardship code in 2010). After the financial crisis, the European Commission also looked into corporate governance, and the discussion ended with the Shareholder Rights Directive II in 2017.

In accordance with the public debate interest in sustainable development, the concept of corporate social responsibility (CSR) has become prominent again (Liang & Renneboog, 2017; Ioannou & Serafeim, 2012). This concept refers to a company's voluntary contribution to sustainable development that goes beyond any legal

requirements. During the 1990s, many companies were forced to react to criticism of corporate practices and bad publicity. Thus, they started programs in the economic, environmental, and social fields of sustainability to transform their business models (Graves & Waddock, 1994). CSR is similar to the acronym of ESG developed by financial institutions on behalf of the UN initiative on sustainable finance. By enlarging the content explicitly to governmental issues, ESG is the more expansive terminology. Hence, it became the standard term in financial accounting research (Gillan et al., 2021). If institutional equity investors are supposed to play an important role in reaching the SDGs by performing control functions, reliable information on these activities must be disclosed (Amel-Zadeh & Serafeim, 2018; García-Sánchez, 2020). Accordingly, an important landmark in fostering institutional investors' engagement in the field of long-term sustainable value creation is the emergence of CSR/ESG disclosure initiatives.

CSR/ESG Reporting to Institutional Investors: An Overview

According to the growing number of signatories to the PRI initiatives, many institutional investors are on their way to improve firms' economic, environmental, and social performance (David et al., 2007; Dimson et al., 2015; Clark & Crawford, 2012). However, disclosure on CSR/ESG activities varies broadly around the world. In the beginning, most of the reports provided to investors were published voluntarily and in a non-standardized form. The focus of information was on environmental aspects. Nowadays, the basic structure of sustainability reports using the ESG factors is broadly accepted. Furthermore, private reporting initiatives improved the quality of CSR/ESG disclosure. Among others, the most important initiators and their initiatives are given below:

- The Global Reporting Initiative (GRI) is an independent international organization that supports companies and governments in

sustainability reporting. The framework mainly consists of three elements: sustainability reporting guidelines, protocols, and sector supplements. Since 1997, when the GRI first developed, it has found a growing acceptance. According to recent studies, nearly 93% of the world's largest corporations use these standards (GRI (ed.), 2021; KMPG (ed.), 2020).

- The International Organization for Standardization (ISO) is an independent and non-governmental organization that develops and publishes international standards in various fields. Companies and individuals cannot become an ISO member. ISO 26000 is the standard for social responsibility. This standard was launched in 2010. It is not certifiable as it does not contain requirements. ISO 2600 consists of seven principles: accountability, transparencies, ethical behavior, respect for stakeholder interests, respect for the rule of law, respect for international norms of behavior, and respect for human rights (ISO (ed.), 2021).
- The United Nations Global Compact (UNGC) is a corporate sustainability initiative. The participants in the initiative involve over 9500 companies in 160 countries. The UNGC supports companies in taking strategic actions toward the SDGs with particular attention to

collaboration and innovation (UNGC (ed.), 2021).

- The Organisation for Economic Co-operation and Development (OECD) is a forum in which governments share experiences and work together on problems. This organization also analyzes data to understand what drives economic, environmental, and social changes. The OECD has published non-binding principles as a standard for responsible business practices and provides guidance on how to disclose information on the wide range of business ethics (OECD (ed.), 2011).

In contrast to these voluntary ESG disclosure initiatives, an increasing number of countries are opting for mandatory disclosure regulation on sustainability activities (Krueger et al., 2021). The map in Fig. 4 provides an overview on this development. Although institutional investors are dominating equity markets in the United States (see Fig. 3), ESG/CSR reporting on ESG by US companies is not mandatory. Hence, the content of sustainability reports is left to companies' discretion (for the analysis of market reactions see Serafeim & Yoon, 2021).

Currently, the European Union (EU) is performing a leading role in enhancing mandatory disclosure on CSR/ESG (Matos, 2020).

Institutional Investors, Fig. 4 World map for countries with mandatory ESG disclosure regulations up to 2016

agree on extending the definition of green bonds to all bonds whose funds are used to finance socially responsible activities (ESG factors). However, in some context, the term of GSS bonds (green, social, sustainability) is used (e.g., CBI (ed.), 2020).

Basically, green bonds differ from standard bonds by being labeled by the issuer: Funds generated by green bonds are earmarked to finance sustainable activities (Park, 2018). Since social responsibility is integrated in the terms of the financial instrument, the governance structure of green bonds is simpler in comparison to ESG equity investments. Institutional investors can monitor projects *ex ante*, have limited downside risks due to exit options on secondary bond markets, and rank *pari passu* to other bond investors in bankruptcy. The emergence of green bonds seems to be a great success story: At the end of 2020, the sustainable debt market had reached USD1.7tn, and almost 10,000 instruments had been issued under GSS labels since 2006 (CBI (ed.), 2021). However, investors in green bonds face the risk of greenwashing, since the issuer's promise to fund socially responsible activities is open to fraud (Bagnoli & Watts, 2020).

The success of green bonds was highly facilitated by the emergence of frameworks set by private governance regimes (Boffo & Patalano, 2020; Park, 2018): the Green Bond Principles, Climate Bonds Initiative (CBI), Sustainability Linked Loan Principles, and green bond indices. Since the long-term future of green bond markets clearly depends on the attractiveness for institutional investors, public standard-setters are considering the regulation of the green bond market. Again, a leading role is performed by the EU: In 2018, the action plan on sustainable finance was adopted by the European Commission. Based on this plan, an EU taxonomy to determine whether an economic activity is environmentally sustainable and meets minimum social safeguards is developed, and an EU Green Bond Standard is designed (Zetzsche & Anker-Sørensen, 2021; Schuetze & Stede, 2021). These political initiatives will support institutional investors' role in the sustainable finance revolution.

Institutionalism

Description

Within the broader area of organizational studies, institutional theory is a major theoretical perspective. It is used to understand organizational behavior as situated in and influenced by its environment. Organizations operate in a social environment that changes, as a result of new laws, the emergence of new standards, rules or norms, new patterns of behavior, and new participants. Institutional theory seeks to explain how elements such as structures, processes, and professions are created and diffused within and between organizations (Greve 2003, p. 172). It asserts that institutional environment has often more profound impact on the development of those elements than market pressures (Meyer and Rowan 1977), and, as such, it explains organizational behaviors that defy economic rationality (Suddaby 2013). The reason for the power of noneconomic drivers is that organizations are striving for legitimacy (see ► [“Legitimacy Theory”](#) and ► [“Social Legitimacy”](#)) with their constituencies. Legitimacy facilitates access to resources from the environment becoming crucial for organization survival (Deephouse 1996; Mizruchi and Fein 1999).

Institutions

Institutions can be understood as the “framework within which human interaction takes place” (North 1990, p. 4) and as systems “of rules, beliefs, norms and organizations that together generate a regularity of social behavior” (Greif 2006, p. 30). They comprise cultural-cognitive, normative, and regulative elements (Scott 2014, p. 56), taking form of formal rules and unwritten codes of conduct (North 1990, p. 4) and backed by a set of rewards and sanctions (Jepperson 1991, p. 145). Institutions define what is acceptable and unacceptable imposing constraints on organizational behavior. They also promote desired conduct providing guidelines and resources. Institutions are by definition durable (or sticky) (Colyvas and Jonsson 2011) and, by being transmitted across time, maintained and reproduced, provide solidity, and reduce uncertainty within social systems (Scott 2014, p. 57). They provide

replicability of social forms and norms and serve to save resources required in the organizing of human activity (Bondy 2009). In their own right, however, institutions themselves also undergo changes, both incremental and revolutionary (Greenwood and Hinings 1996).

The origins of institutional theory date back to the end of the nineteenth and beginning of the twentieth centuries and works of Marx, Weber, Cooley, Mead, Veblen, and Commons. However, only recently institutional theory experienced a remarkable renaissance (Scott 2004). The evolution of institutional theory can be divided into three main stages: (1) old institutionalism, (2) new institutionalism, and (3) reconciliation.

Old Institutionalism

The first stage in institutional theory is referred to as the “old” institutionalism – institutionalism that encompasses detailed qualitative case studies of organizations in the 1950s and 1960s (Suddaby 2013). In the old institutionalism, “issues of influence, coalitions, and competing values were central, along with power and informal structures” (Greenwood and Hinings 1996, p. 1022). The stage was demarcated by the publication of Selznick’s classic study of the Tennessee Valley Authority (TVA) in 1949. Agency leaders co-opted local officials into the decision-making process to gain local support. Co-optation is defined as “the process of absorbing new elements into the leadership or policy-determining structure of an organization as a means of averting threats to its stability or existence” (Selznick 1966, p. 561 as cited in Reed 2009, p. 13). In the case of TVA, the process had unintended consequences, as local officials changed organizational goals to serve their private interests (Rollag 2018).

While Selznick agrees that organizations can be rationally structured to attain certain goals, they also have natural, nonrational dimension. There are two sources of this nonrationality: (1) individuals who bring other commitment to the organization and do not act purely within their formal roles and (2) informal organizational structures that link participants with each other and

with external actors (Scott and Davis 2015). The author notes that organizational structures adapt based on actions of individuals and on pressures from external environment (Selznick 1996).

Institutionalization refers to this process of adaptation and happens over time to all organizations, though to different extents. As Scott and Davis observe: “Institutional commitments develop over time as the organization confronts external constraints and pressures from its environment as well as changes in the composition of its personnel, their interests, and their informal relations” (Scott and Davis 2015, p. 74).

There is no agreement, however, on the term or the issue. Selznick postulated a distinction between organizations that are tools designed to achieve certain goals and institutions, i.e., institutionalized organizations that take on a distinctive character (Selznick 1996) and become “valued, natural communities concerned with their own self-maintenance as ends in themselves” (Scott 1987, p. 494). The essence of the institutionalization process is “the infusion with value beyond the technical requirements of the task at hand” (Selznick 1996, p. 271). It is leadership’s task to choose and protect this distinctive values (Scott and Davis 2015).

New Institutionalism

The second stage – the new institutionalism (or neo-institutionalism) – is demarcated by the publication of two seminal papers: Meyer and Rowan’s “Institutionalized Organizations: Formal Structure as Myth and Ceremony” in 1977, followed by DiMaggio and Powell’s “The Iron Cage Revisited: Institutional Isomorphism and Collective Rationality in Organizational Fields” in 1983 (Suddaby 2013). Both the old and the new approaches focus on the role of the environment in shaping organizational reality and are skeptical about the rationality of organizational behavior. They both view “institutionalization as a state-dependent process that makes organizations less instrumentally rational by limiting the options they can pursue” (DiMaggio and Powell 1991, p. 12). The new institutionalism in

organizational studies, however, has generated a series of changes of focus. These changes include a shift of focus from vested interest to legitimation, from informal structures to symbolic role of formal structures, from change to persistence, from organization to organizational fields, and from values, norms, and attitudes to scripts, schema, routines, and classifications (DiMaggio and Powell 1991). In the new institutionalism, institutions are viewed as “collective cognitions or shared assumptions that, over time, acquire a degree of social concreteness. That is, they become taken-for-granted and, as a result, constrain organizational behavior” (Suddaby 2013, p. 381).

Initially scholars of new institutionalism focused on the question of legitimacy and growing homogeneity among organizations. Meyer and Rowan (1977) find that in the pursuit to gain legitimacy, companies are “prone to construct stories about their actions that correspond to socially prescribed dictates about what organization should do” (Mizruchi and Fein 1999, p. 656). Thus, once again, it is not economic rationality that defines the rules of behavior but myths (taken-for-granted assumptions) about what constitutes economic rationality (Suddaby 2013). While legitimacy improves access to resources from the external environment, reduces turbulence, and maintains stability, it is not the whole story. The incorporation of institutional myths in organizational structures is useful as they enhance the organization’s prospects for survival (Meyer and Rowan 1977). The research has established, however, that organizations often conform to social expectations only ceremonially and not in terms of substance. Formal structures adopted as a result of institutional pressures are often decoupled from substantive matters – the core technical activities (Meyer and Rowan 1977).

In search of legitimacy (social fitness), organizations structure themselves according to the characteristics of the environment they operate in and particularly other organizations operating in the field. This facilitates organizational isomorphism – the growing similarity of organizations in a field. Organizational field is defined as “organizations that, in the aggregate, constitute a

recognized area of institutional life: key suppliers, resource and product consumers, regulatory agencies, and other organization that produce similar services and products” (DiMaggio and Powell 1983, p. 148). In the existing literature, two types of organizational isomorphism are identified – competitive and institutional (DiMaggio and Powell 1983; Deephouse 1996). The former results from firms’ actions in line with market competition, while the latter involves “organizational competition for political and institutional legitimacy as well as market position” (Mizruchi and Fein 1999, p. 657).

As organizations respond to the same institutional pressures and constantly interact with each other, their structures become increasingly homogeneous (DiMaggio and Powell 1983). Consequently, DiMaggio and Powell (1983) distinguished three further mechanisms at work, revealing how new behavior patterns diffuse among organizations resulting in increasing their similarity. These mechanisms are coercive, mimetic, and normative isomorphism. Coercive isomorphism constrains organization activities by way of formal and informal pressures. These pressures come from parties upon which the company is dependent, including regulators and shareholders, as well as from society at large. Mimetic isomorphism is a response to institutional uncertainty. It refers to organizational tendency to mimic practices of more legitimate or successful peers, either intentionally or unintentionally through influence of consultants and employees hired from other companies. Finally, normative isomorphism is a result of professionalization of the organizational field through similar managerial education and growth of professional networks. DiMaggio and Powell note that while the institutionalization process involves often the interplay of all three isomorphism mechanisms, they may lead to different outcomes.

Reconciliation

The most recent evolution of institutional theory can be described as a reconciliation between the

old and new institutionalism. The major criticism of neo-institutionalism focused on its initial assumptions of stability of structures, organizational passivity (Hirsch and Lounsbury 1997), and isomorphism among organizations. Little empirical evidence has been found to support this view (Kraatz and Zajac 1996). The reconciliation approach can be seen in Greenwood and Hinings (1996) where it is proposed that the old and the new institutionalism can be combined in order to develop “a model of change that links organizational context and intraorganizational dynamics” (p. 1024). Subsequently, the scope of the theory was expanded to account for the transformation and change of institutions, as well as the heterogeneity of actors and practices in fields.

As pointed by Eisenstadt (1964), institutionalization is a process in any social system and serves to create the possibilities for change. In the course of the conceptual development of institutionalization, reconciliation ideas, the issues of inertia, and path dependence emphasized by the conventional perspective started to be replaced by the attempts to identify “the determinants of organizational flexibility and change” (Chizema 2008, pp. 363–364).

Changes in the institutional environment require a series of adaptations at the microlevel (Aoki 2007). Greenwood and Hinings (1996) point out that interplay of contextual forces (both market and institutional) and intraorganizational dynamics facilitates radical organizational change. The pace and response to institutional change at the organizational level is determined by both the institutional environment of a region or country embedded in the model of economic system and the organizational context including interests and values of particular groups, power dependencies, and organizational capabilities (Greenwood and Hinings 1996).

Accepting a distinction between organizations and institutional environments, it is clear that not all organizations will move in lockstep with changes in the institutional environment. Oliver (1991) offers framework of organizational strategic responses to institutional processes that include:

1. Acquiescence strategy
 - a. Habit – unconscious adherence to taken-for-granted rules
 - b. Imitation – mimicking institutional models
 - c. Compliance – conscious obedience to institutional requirements in anticipation of specific self-serving benefit
2. Compromise strategy
 - a. Balance – balancing the pressures from of multiple stakeholders
 - b. Pacifying – partial conformity and placating institutional elements
 - c. Bargain – negotiating with constituents
3. Avoidance strategy
 - a. Concealment – disguising nonconformity
 - b. Buffering – loosening institutional attachments, for example, by decoupling internal work activities from formal structures and external assessment (Meyer and Rowan 1977)
 - c. Escape – modification of goals and activities, or domains
4. Defiance strategy
 - a. Dismissal – ignoring social expectations and norms
 - b. Challenge – contesting the rules
 - c. Attack – assaulting the sources of institutional pressure
5. Manipulation strategy
 - a. Co-option – importing influential stakeholders
 - b. Influence – shaping rules and requirements
 - c. Control – dominating the rules setting processes

Organization's response to institutional pressures depends on its willingness and ability to conform.

The former may be reduced by organizational skepticism about legitimacy of particular institutional demands, mismatch between organizational objectives and social expectations, and attempt to maintain control over internal processes. The latter is restrained by limited resources or capabilities to address institutional pressures, conflicting stakeholders' demands, and, finally, lack of awareness of rules and social expectations.

CSR from the Perspective of Institutional Theory (See ► **“Corporate Social Responsibility and Institutional Theory”**)

One area of institutional change and distinct organizational response can be seen in the field of corporate social responsibility (CSR). Differences in CSR adoption on the company level result from national differences in the understanding and perception what CSR means (Freeman and Hasnaoui 2011). Dahlsrud (2008) argues that CSR is a social construct which functions in a certain way in a given context and cannot be universally defined. CSR can be understood as the set of practice and policies adopted by a country but may also be viewed at the voluntary action, which starts “where the law ends” (Davis 1973, p. 313). Despite the common underlying assumption of the voluntariness of CSR, it is best understood as a type of “voluntary regulation” – i.e., a type of regulation that imposes itself on organizations (Sheehy 2014). At an operational level, CSR is well developed both with respect to institutional guidelines and requirements and managerial processes (Roszkowska-Menkes and Aluchna 2017). This institutionalization is an adoption of particular norms for different policies and procedures such as occupational health and safety, respect for human rights, antidiscrimination, anti-corruption, product safety, or environmental protection (Sheehy 2014). Additionally, institutionalization of CSR is supported internationally by a range of recognized disclosure standards and guidelines (CDP, GRI, IIRC, SASB) (Sheehy 2019).

The adoption of CSR principles illustrates the case of the diffusion and institutionalization of change in formal organization structures in response to pressures exerted by four actors: lawmakers, market makers, model makers, and governance actors (Aluchna and Roszkowska-Menkes 2017). This process is influenced by a set of institutional factors, as well as a number of organizational characteristics that impact the company's motivation and ability to conform to new requirements. These are as follows: first, the institutional context which impacts the adoption

of CSR refers to the shape of the political system and election regime, economic model (market liberal versus coordinated economy) (Jensen and Berg 2012; Kinderman 2009), and ownership structure including the role of families versus financial investors (Kang and Moon 2012), norms on mobility, employee rights and trade union activity (Deakin and Reberlioux 2009; Deeg and Jackson 2007; Gourevitch 2003), time orientation, and collective versus individual behavior (Doidge et al. 2007). The dynamics of organizational response to institutional context of CSR is revealed in research by Matten and Moon (2008) who distinguish European implicit CSR versus US-based explicit CSR. Second, the adoption of CSR may be stimulated or limited by organizational characteristics that determine the demand and supply for CSR (McWilliams and Siegel 2001). These include the stakeholder relations (Barnea and Rubin 2010) and their residual rights (Harjoto and Jo 2011), which influence the governance structure and determine the goal prioritization (Mackenzie 2007), attainment discrepancy, and, finally, organizational slack (Arora and Dharwadkar 2011).

Summary

Institutional theory, as one of the major theoretical frameworks in organizational studies, views organizations, their structures, practices, and standards of behavior as determined by rules and norms originating from their environment. As such it is often harnessed in the studies explaining diffusion patterns of CSR among organizations.

While the old institutionalism focused on institutionalization understood as “value infusion” and driven by individual actors within organizations and informal structures, the new institutionalism shifted toward formal, homogeneous, and often symbolic structures adopted across organizations in result of pressures from the environment. The most recent, reconciliation perspective in institutional theory acknowledges both internal and external sources of institutionalization. Organizations striving to attain legitimacy are strongly influenced by taken-for-granted social dictates.

Their responses to coercive, mimetic, and normative pressures however vary. The reconciliation approach rejects institutional determinism and proposes that strategies utilized by organizations to address social expectations depend on the interplay between institutional factors and organizational characteristics.

Integrated Management Systems

Maja Glogovac
Department of Quality Management and Standardization, Faculty of Organizational Sciences, University of Belgrade, Belgrade, Serbia

Definition/Description

Integrated management system is a set of concurrently planned, implemented, and maintained

management systems with regard to multiple disciplines, such as quality, food safety, information security, environment, and occupational health and safety. This is an array of interacting elements that are interrelated and that form an organization's structure, policy, objectives, processes and way of the practice, as well as rules, roles, responsibilities to achieve objectives related to needs and expectations of different stakeholders, depending on disciplines included within a scope of the integrated management system. Integrated management system can be implemented in every organization, regardless its structure, age, industry, etc., and can encompass the organization as a whole, but also the specific parts of the organization.

By integrating multiple management systems, rather than implement and maintain them separately, an organization could have a significant benefits such as elimination of redundancy and reduction in bureaucracy, consistency in approach, optimization of processes and resources, reduction in maintenance of management systems, consolidation of assessments, facilitation of decision-making, etc. which enhance the organization's capacity to have a systematic process that is capable of absorbing any new or changed requirements.

Introduction

The environment in which companies now operate is less secure and more complex (Thomas et al. 2016), where the customers worldwide increasingly demand products that are sustainable (Kara et al. 2014). To compete successfully, companies have to find ways to ensure customers about the sustained quality of their outputs. Therefore, there are a growing number of standards for management systems that contribute to sustainable development (Nadae et al. 2019) and which promote the PDCA (Plan-Do-Check-Act) model of quality improvements. The challenge is to integrate them into one effective and efficient system.

Integrated Management Systems

Every organization goes toward accomplishing some objectives related to many interested and

affected parties' needs and expectations (ISO 2018). That is why organizations need strategies for continuously sustaining stakeholder support, based on making decisions and managing their recourses, which is often referred to as a management system (ISO 2018). The management system of an organization is an array of interacting elements that are interrelated and that form an organization's structure, policy, objectives, processes, and way of the practice, as well as rules, roles, responsibilities to achieve those objectives (ISO 9000:2015). As such, the management system can be related to a single discipline or various disciplines, for example:

- Quality management, as part of a management system with regard to quality aiming at increasing level of satisfying customer needs about organization's outputs (ISO 9001:2015)
- Environmental management, as part of a management system that seeks to provide organizations with an outline to protect the environment and respond to changing environmental conditions in coherence with socioeconomic needs (ISO 14001:2015)
- Occupational health and safety management, as part of a management system aiming to enable organizations to enable safe and healthy work environment by prevention from injuries and ill health, as well as by proactively upgrading occupational health and safety performance (ISO 45001:2018)
- Food safety management, as part of a management system with the aim to enhance organizations' ability to manage hazards related to food safety in order to ensure food safety (EN ISO 22000:2018)
- Information security management, as part of a management system that refers to continuous improvement of an information security management system (ISO/IEC 27001:2013)
- Many other disciplines that could be part of organization's overall management system

Each management system can be implemented in every organization, regardless its structure, age, industry, etc. The scope of each management system can encompass the organization as a whole, but also the specific parts of the organization, or

one or more functions across a group of organizations (ISO 9000:2015).

When organization goes toward sustainable improvements in more than one discipline at the same time, it could integrate the elements of different managements systems to manage them more efficiently. Many standards for different management systems issued by ISO (International Organization for Standardization) have the same core structure with similar elements that enable their integrated establishment, documentation, implementation, and maintenance. For example, when establishing the organization's structure, roles, and responsibilities, it is practically to be done for several disciplines at the same time, or when document processes it is more efficient to take into account all the relevant aspect concurrently. This could include, for example, defining all the possible risks during operation: those related to the quality of organization's outputs as well those that could affect environmental, or those that could lead to the unsafe and unhealthy workplaces, or those that could endanger information security, etc. Also, when establishing organizational performances, all the disciplines included in the overall management system could be considered together and in the mutual relationship. When auditing or reviewing the management system, the better overview could be achieved by considering all the relevant disciplines as one integrated system. And so on, each element of management system for different disciplines could be better managed if it was integrated with other elements within the same organization. ISO (2018) has developed the same high level structure (HLS) for the management systems standards to facilitate their mutual integration. It also covers identical text for management system standards and common core management system terms and definitions. This enables organizations to apply quality management standards as integrated units rather than separated parts.

Integration of multiple management systems, rather than implement and maintain them separately, could have significant benefits for an organization (ISO 2018):

- Development of the organization's capacity to have a systematic process that is capable of absorbing any new or changed requirement

- Elimination of redundancy, for example, in area of process documentation
- Consistency in approach to communication, decision-making, setting priorities, measurement and monitoring, etc.
- Reduction in bureaucracy
- Optimization of processes and resources
- Reduction in maintenance of management systems that need to be maintained concurrently
- Consolidation of assessments, since the inter-relationship among the processes are better understood and managed which can lead to more in-depth assessments
- Facilitation of decision-making, since the organization now has a more complete view of the needs and business performances

Integration of management systems depends on a various factors, including human and material resources and costs, which can cause some challenges or even difficulties in the implementation. Some of them could be related to the diversity of constituent management systems, employees' opposition, deficiency of resources, cultural aspects but also post-implementation difficulties (Asif et al. 2008).

Summary

In today's competitiveness environment, there is a growing number of standards for management systems that contribute to sustainable development (Nadae et al. 2019), where the challenge for organizations is to integrate them into one effective and efficient system. Management systems today cover many areas, such as quality, food safety, information security, environment, and occupational health and safety. By integrating multiple management systems, rather than implementing and maintaining them separately, an organization could have significant benefits such as elimination of redundancy and reduction in bureaucracy, consistency in approach, optimization of processes and resources, reduction in maintenance of management systems, consolidation of assessments, facilitation of decision-making, etc. ISO has put significant effort to develop the same high level structure (HLS) for the

management systems standards to facilitate their mutual integration. It also covers identical text for management system standards and common core management system terms and definitions. This enables organizations to apply quality management standards as integrated unit rather than separated parts.

Definitions

Integrated quality and environmental management (IQEM) is a management approach that ensures quality in developing and utilizing natural resources while also considering political, economic, social, and governance factors. IQEM employs total quality management techniques to prevent environmental degradation (AENA 2023) and is an adaptive engagement with a collaborative assessment of issues, policies, and measures that include stakeholders' holistic perspectives (Antunes and Santos 1999). Quality management systems, such as ISO 9001, are put in place to attain high-quality products and procedures. IQEM also encompasses environmental management under ISO 14001 and promotes an inclusive approach that considers the environment's human and nonhuman components (von Ahsen 2013). The IQEM philosophy emphasizes profitability and sustainability, and it can lead to advantages like reduced audit costs, streamlined operations, sound decision-making, simple employee training, and effective resource management (Roy and Ghose 2016). IQEM seeks to involve all stakeholders in high-quality environmental practices by connecting all efforts to promote environmental resource management and stewardship, including the reuse of products generated from raw materials in an economically efficient manner (Vivancos Calvet et al. 2015).

Introduction

Global warming and the rising levels of environmental contaminants have an impact on environmental groups as sustainable development (SD) and globalization receive more attention (Zutshi and Sohal 2004). An integrated management system combines two or more systems to create a cohesive, effective system (Nunhes et al. 2016). Integrated MSs have been viewed as a helpful technique for addressing interdependencies across various management systems (Ahsen 2014). For instance, by utilizing energy-efficient technologies and minimizing the use of natural resources, environmental management (EM) practices improve

environmental performance (EP) (Tung et al. 2014). According to Djekic (2015), EM techniques enhance the EP of all environmental factors and aid in water utilization, which is excellent for wastewater management.

The integrated management system focuses mainly on the quality of environmental and work and health safety management systems (Asif et al. 2009). The level and choice of integration are influenced by the system norms about various aspects of quality, environment, the hierarchical arrangement of existing management systems, maturity regarding IMS constituents, and prevailing cultural aspects, such as willingness to improve continuously and management involvement (Abrahamsson et al. 2010).

To ensure a sustainable and environmentally friendly method of maintaining environmental quality, a highly integrated system of management structures should reflect the allocation of responsibilities to all levels for the development, implementation, and maintenance of plans that affect each specific area of management (Sanz-Calcedo et al. 2015).

Benefits of Integrating Quality and Environmental Systems

Integrated quality and environmental management (IQEM) is an approach that combines quality management principles with environmental management practices to promote sustainable and responsible business practices. Integrating ISO 9001 and ISO 14001 will highlight overlapping duties or unnecessary duplication by meeting all the standard requirements with one set of policies and procedures, resulting in reduced duplication in business operations that will be simpler to administer and maintain (Europe Direct 2007). It improved adherence to the law, diminished risk of civil and criminal liability, and generated savings by avoiding the cost of hazardous material cleanup. The benefits of IQEM can be significant for organizations that adopt this approach. IQEM improved efficiency which can lead to streamlined processes, reduced waste, and increased productivity, which can improve efficiency and reduce costs. IQEM adoption can show an organization's dedication to

sustainability and ethical environmental behavior, which can improve its reputation and brand image. IQEM can help organizations comply with environmental regulations and quality standards, reducing the risk of fines and legal penalties. IQEM can help organizations identify and manage risks related to environmental issues and quality control, improving their ability to respond to potential crises. The advantages of using an environmental management system include notably better business organization, lower pollutants, and lower expenses (Vadaştăreanu et al. 2015). In addition, it decreased the time and cost required to implement the project, made design changes that saved money, increased project acceptance, prevented negative effects and legal violations, improved project performance, and avoided treatment and cleanup expenses. By adopting IQEM, organizations can meet customer expectations for sustainable and responsible practices, which can enhance customer satisfaction and loyalty. IQEM can promote a culture of sustainability and responsibility, which can increase employee engagement and satisfaction (Ramdhan et al. 2022). By reducing waste and increasing efficiency, IQEM can lead to significant cost savings over time. Overall, IQEM can help organizations achieve sustainable growth while promoting responsible environmental practices and improving quality control.

Cost of Integrated Quality and Environmental Management

Integrated quality and environmental management (IQEM) can provide numerous benefits to organizations, but there may be some costs associated with implementing and maintaining this approach (EPA 2022). Some of the costs of IQEM may include training and education employees to understand the principles and practices involved in IQEM, which can incur costs. Organizations may need to invest in technology and tools to support IQEM, such as software for tracking environmental metrics and quality control data (Primavera et al. 2019). Organizations may need to engage external auditors to verify compliance with environmental regulations and quality standards, which can incur fees.

Organizations may need to establish processes for monitoring and reporting on environmental and quality metrics, which can require additional resources and staff time. Depending on the complexity of an organization's operations, the implementation of IQEM may require additional resources and staff time, which can incur costs. Despite these potential costs, IQEM can provide significant benefits in terms of improved efficiency, enhanced reputation, compliance with regulations, better risk management, increased customer satisfaction, improved employee engagement, and cost savings. From a company's social responsibility standpoint, it will create an integrated management structure that yields long-term economic rewards (Sanz-Calcedo et al. 2015). In the long run, the benefits of IQEM may outweigh the costs, making it a sound investment for organizations committed to sustainability and responsible business practices.

Ecosystem Integrity Relating with IQEM

Ecosystem integrity is the concept of maintaining the health and resilience of ecosystems, ensuring that they remain intact and functional over time. The integrity of an ecosystem can be quantified by the extent to which an ecosystem's component attributes, such as the composition, structure, and functions, remain in their historical ranges of variation and continue to perform as intended (Nicholson et al. 2021). Integrated quality and environmental management (IQEM) can play an important role in promoting ecosystem integrity by incorporating environmental sustainability principles into an organization's operations. IQEM involves the integration of quality management principles with environmental management practices, creating a comprehensive approach to sustainability that considers both environmental impact and quality control (Bridgewater et al. 2014). This approach can help organizations to identify and address potential environmental risks and reduce negative impacts on ecosystems. By adopting IQEM, organizations can take steps to reduce pollution, conserve natural resources, and protect biodiversity (Di Marco et al. 2019). For

instance, an organization that produces goods may implement an IQEM program to reduce waste by recycling materials and using more sustainable packaging. This can help to reduce the amount of waste generated, reduce the use of virgin resources, and minimize the negative impacts on ecosystems. IQEM can also help organizations to better understand the interconnectedness of environmental systems and the impact of their operations on those systems. The human footprint index (Williams et al. 2020), the Ecosystem Intactness Index, the Forest Landscape Integrity Index (Grantham et al. 2020), the Cumulative Human Pressure on Marine Ecosystem (Halpern et al. 2019), fish abundance and biomass, coral cover and composition, and other indicators of human pressure can all be used to measure the integrity of an ecosystem. By incorporating this understanding into their decision-making processes, organizations can identify ways to reduce their environmental impact and contribute to the preservation of ecosystems. Overall, ecosystem integrity is an important aspect of sustainability, and IQEM can play a critical role in achieving this goal. By promoting sustainable practices that reduce negative impacts on ecosystems, organizations can contribute to the preservation of natural resources and promote a healthier environment for future generations (FAO 2023).

Environmental Risk Management Relating to IQEM

Integrated quality and environmental management (IQEM) is a comprehensive approach to sustainability that incorporates quality management principles with environmental management practices. Environmental risk management is a key component of IQEM, as it helps organizations to identify, assess, and mitigate environmental risks associated with their operations. Various forms of environmental risk management include assessments of the risks from natural disasters, pollution, and safety (Sarfraz et al. 2018). Thus, an ideal ERA model should enable investigating, elucidating, and predicting environmental system reactions to changes caused by naturally

occurring and human-based stressors with imperfect knowledge (Whelan et al. 2014). IQEM and environmental risk management are closely related, as both approaches seek to promote sustainability by minimizing negative environmental impacts. By incorporating environmental risk management into IQEM, organizations can take a proactive approach to managing environmental risks and promoting sustainable practices. IQEM can help organizations to identify and prioritize environmental risks, develop mitigation strategies, and track progress toward sustainability goals. For instance, an organization that produces goods may implement an IQEM program that includes a risk assessment of the environmental impacts associated with their manufacturing processes. Based on the assessment, the organization can develop strategies to reduce emissions, conserve resources, and improve waste management practices. IQEM can also help organizations to integrate environmental risk management into their quality control processes (Shah et al. 2019). By incorporating environmental considerations into quality management, organizations can ensure that their products and services meet environmental standards while also improving customer satisfaction and brand reputation. Overall, IQEM and environmental risk management are complementary approaches that can help organizations to achieve sustainability goals while minimizing negative environmental impacts. By adopting an integrated approach to quality and environmental management, organizations can promote sustainable practices and enhance their overall performance.

Tools in Environmental Management

Techniques for evaluating human activities' environmental impact are urgently needed to lessen our influence on the environment (Loiseau et al. 2012). Choosing actions to lessen the total environmental impact might be challenging; thus, a methodical approach is required (Andersson et al. 2016). However, various environmental management tools have been created to influence organizational structures, processes, and practices.

These include life cleaner production, cycle assessment, environmental impact assessment, waste management, material flow analysis, substance flow analysis, physical input-output table, ecological footprint analysis, ecological network analysis, and environmental and landfill management (Loiseau et al. 2012).

Life cycle assessment (LCA) is a tool for environmental management that considers the use of resources and energy as well as the effects on the environment during an item's entire life cycle, including the collection of raw materials, production, conversion, distribution, usage, recovery, and disposal (Robertson 2014). EIA processes are undoubtedly a valuable proactive environmental management tool (Bruschi and Coratza 2018).

Bilateral, regional, or multilateral environmental agreements (MEAs) are a crucial international tool for addressing specific environmental challenges. They play an essential part in the overall structure of environmental regulations and are used to reinforce management techniques for integrated coastal zone management, National Adaptation Programs of Action, and Protected Areas Frameworks (Primavera et al. 2019).

Environmental impact assessment (EIA) is the methodical investigation of unintended consequences of a development project or program to reduce adverse consequences and optimize advantageous ones (Jay et al. 2007). Adopting cleaner production is a crucial component of EIA and EMS. Cleaner production emphasizes the use of more eco-friendly technology with fewer natural resources. This process aims to stop waste at its source and ensure that less waste is produced during manufacturing (El-Haggar 2007).

Sustainable waste management systems are used as cutting-edge management techniques influencing air quality to reduce environmental problems and save resources (Demirbas 2011). Waste management is a big issue in sub-Saharan Africa (Asase et al. 2009), mainly as a result of the absence of recycling infrastructure, skilled workforce, and other relevant issues resulting in over 4.4 million tons of solid waste being "mis-managed" across the continent of Africa (Jambeck et al. 2018).

These environmental management tools have great potential to support environmental policy-making to ensure a sustainable environment for all.

Stakeholder Involvement in Quality Environmental Management

Stakeholder involvement in quality environmental management aims to enhance communication among parties (including the proponent) to support sustainable development and improved decision-making (DEAT 2002). Stakeholder involvement is a cornerstone of sustainability. A company needs to be able to communicate with its external stakeholders if it wants to remain relevant and better serve its customers (Cort 2022). They carry out the study and ascertain the project's potential effects, scope, and methods for mitigating them. The government is requested to approve the final EIA report that they have compiled (Babu 2016). Stakeholders have the power to influence the resources and environmental decisions made by the company. Participants in the business process are known as stakeholders. Employees are an example of internal stakeholders, whereas community members and advocacy organizations are examples of external stakeholders (Rakowski 2020). Businesses and industry, kids and teens, farmers, indigenous peoples, their communities, local governments, nongovernmental organizations, the scientific and technological community, women, workers, and trade unions are the main groups involved in high-quality environmental management. By taking into account more thorough information inputs, stakeholder involvement can improve the quality of environmental decisions (Reed 2008).

Need for an Integrated Management System

Integrated environmental management is defined by Buhrs (1995) as the management of the environment that takes account the complex and interconnected nature of environmental

management. Integrating all aspects involves all multidisciplinary sectors and the public in practicing and educating the lawmakers, government, local communities, and the public on environmental problems, as well as noting the environmental impact assessment and mitigation to maintain sustainability. Without integrated management of the environment and with the climate impact on our environment today, most all natural resources will face further environmental problems now or later. Establishing an integrated environmental management (IEM) system can aid in advancing sustainability goals. Because the system becomes proactive rather than reactive, this approach will improve environmental performance, and stakeholder engagement is one of the keys to making the concept a reality.

Management Decision

The benefits of integrated environmental management (IEM), according to Margerum (1999), are that better-informed decisions are made when considerable specialist knowledge is integrated. The most crucial element of IEM's functioning structure is the interaction between stakeholders and the general public. As a result, a spectrum of increasing stakeholder involvement in the decision-making process can represent the stakeholder engagement level. For parties involved in the decision-making process, such as scientists, engineers, or other technical professionals, properly sharing knowledge plays a significant role in the process, and good communication is essential.

According to Harding (1998), multidisciplinary approaches are critical to share ideas and considering all possible outcomes or strategies. These possibilities are because decisions are often made in isolation from the larger context, limiting them to specific disciplines. Consequently, communication can influence the management decision-making process. With increased communication among all parties involved, coordination, evaluation criteria, and participant knowledge can be utilized to define goals; implement, monitor, and correct course if necessary; and take measures or make necessary

modifications. Because potential issues are addressed during the planning and decision-making process, environmental quality is improved, and implementation efficiency is raised.

Due to its complexity and dynamic nature, environmental management demands flexible, transparent decision-making considering various information and values. Stakeholder involvement in making environmental decisions is increasingly sought-after and incorporated into national and international policies (Stringer et al. 2008). However, the type of process leading to the decisions has an essential effect on the quality of decisions produced through stakeholder engagement (Reed 2008).

According to Richards et al. (2004), stakeholders' involvement, with public input, can put quality environmental management concepts into action by collaboratively developing and implementing new management strategies. Through initiative and education, stakeholders promote implementation. Stakeholder involvement and integrated environmental management elements, according to Margerum (1999), are not guarantees, but they will increase effective practice, support ongoing initiatives, and create a more detailed model for integrated environmental management. However, this approach will be critical in managing our environment or natural resources.

However, some believe that the claims about stakeholder involvement still need to be met (Reed 2008). Understanding the local area and science through research can be merged to give a more thorough knowledge of complicated and dynamic socioecological systems and processes. Finally, stakeholder engagement must be institutionalized to overcome many inherent restrictions, where relevant participation is considered, developing cultures inside organizations that can trigger systematic stakeholder processes where goals and outcomes are worth taking (Reed 2008).

Summary

An integrated system ensures that any organization can manage its operations and industrial processes environmentally friendly and sustainably

and maintain environmental quality. IQEM aims to help organizations increase their effectiveness and competitive advantage by concentrating on developing particular talents and critical competencies. According to the resource-based view's hypothesis, the management system fosters internal competency growth, organizational learning, and increased effectiveness. With the help of IQEM, organizations can enhance their environmental performance, and there is a definite need for a thorough environmental evaluation that takes into account all aspects of production processes, including difficulties with pollution, energy use, and waste management. Companies should apply ISO 9000 and ISO 14000 to gain a competitive advantage. Stakeholder involvement in the components of the proposed system is taken into account, resulting in sufficient participation and involvement for future progress.

Ignacio Llorente
University of Cantabria, Santander, Spain

Synonyms

Comprehensive corporate reporting; One report;
Single report

Definition/Description

In the last decade, the achievement of integration of financial and nonfinancial reporting has been discussed at various levels, considering the concept “integrated” from the point of view of an integrating spirit in the approach rather than the release of a single report. Integrated reporting refers to a holistic representation of corporate performance regarding financial and nonfinancial information and thanks to the Integrated Reporting (IR) framework by the International Integrated Reporting Council (IIRC), a process that results in one report about value creation, including material information about several aspects of the organization.

Introduction

Corporate disclosure and reporting are the means by which stakeholders, internal and external, can recognize and evaluate organizational behavior. The evolution in the response to the stakeholders’ demands is reflected in corporate sustainability reporting, where the disconnection between the disclosure of financial information and the disclosure of non-financial information has begun to be overcome (Frias-Aceituno et al., 2013a). The difference between the characteristics of these types of information in terms of homogeneity and audience has led to their treatment and evolution being very

irregular. Proof of this is the appearance of a multitude of regulations, codes, guidelines, and requirements (Frias-Aceituno et al., 2013a), which tend to standardize corporate disclosure. This forces a company to be permanently reinforcing its disclosure channels, providing reports of greater length and complexity that make it difficult for the audience to understand them due to the fragmented and disconnected information. In fact, how many reports issued by a company do you read? Do you use skimming and scanning tools when reading all reports? Are you interested in all the information issued in a corporate report?

That is why a decade ago, many listed companies began to release their reports in a combined way, echoing stakeholder requests. Although the publication of an integrated report does not imply ceasing to publish other more specific reports, it can become the main corporate report (“an organization’s primary reporting vehicle”), as assumed in 2011 by the International Integrated Reporting Committee (IIRC). In fact, talking about integrated reporting is talking about Integrated Reporting and IIRC, the institution that has promoted the formalization of this type of integrated reporting. In addition, one cannot talk about integrated reporting without talking about integrated thinking, and this is precisely the long-term vision of the IIRC, which puts integrated thinking (“the active consideration by an organization of the relationships between its various operating and functional units and the capitals that the organization uses or affects” (The IIRC | Integrated Reporting, 2021)) at the center of business practice.

We will review in this entry the evolution and definition of the concept of integrated reporting and its different approaches, with an emphasis on the IIRC framework, promoter of the Integrated Reporting. Subsequently, reference is made to the type of publications in academic literature. Finally, we will talk about the comprehensive corporate reporting system announced in September 2020 by the five leading framework and standard-setting organizations: the CDP (formerly Carbon Disclosure Project), Climate

Disclosure Standards Board (CDSB), Global Reporting Initiative (GRI), International Integrated Reporting Council (IIRC), and Sustainability Accounting Standards Board (SASB). The idea of this initiative is “connect sustainability disclosure standards focused on enterprise value creation to Financial GAAP, with integrated reporting as the conceptual framework linking such sustainability disclosures and Financial GAAP” (Impact Management Project et al., 2021).

Evolution and Definition of Integrated Reporting

The so-called integrated reporting journey begins in the 1990s, when the King Report on Corporate Governance (King I Report), promoted by Mervyn E. King, was published in South Africa. The second edition of the report (King II Report), released in 2002, includes a recommendation on Integrated Sustainability Reporting that reads “a company shall report on its policies and procedures and systems and commitments to the following: social, ethical, safety, health, and environment” (5.1.1.), requiring “an integrated approach” (5.1.2.) (Institute of Directors in Southern Africa (IoDSA), 2002). It is true that the concept “integrated” seems to refer to the integrating spirit in the approach and not so much to the reference of a single report, something that is maintained in the third update of the South African Corporate Governance Code, the King III Report. In its Chap. 9, Integrated reporting and disclosure, it is detailed that integrated reporting means “a holistic and integrated representation of the company’s performance in terms of both its finances and its sustainability. This can take the form of a single report or dual reports” (Institute of Directors in Southern Africa, 2009). In the following decade, the achievement of integration of financial and nonfinancial reporting is discussed in many forums (Dumay et al., 2016). The publication in 2010 of the book entitled *One Report: Integrated Reporting for a Sustainable Strategy* is of special relevance, and it is constituted as another approach to

integrated reporting, in which, as in the King III Report, it is made explicit that “One Report does not mean Only One Report” (Eccles & Krzus, 2010). Eccles and Krzus (2010) defines that one report as “producing a single report that combines the financial and narrative information found in a company’s annual report with the nonfinancial (such as on environmental, social, and governance issues) and narrative information found in a company’s ‘Corporate Social Responsibility’ or ‘Sustainability’ report” (Eccles & Krzus, 2010). After the publication of this book, integrated reporting is considered “a new reporting paradigm that is holistic, strategic, responsive, material and relevant across multiple time frames” (Adams & Simnett, 2011). In this context of paradigm shift, the International Integrated Reporting Council (IIRC) arises, where integrated reporting (IR) is defined as “a process founded on integrated thinking that results in a periodic integrated report by an organization about value creation over time and related communications regarding aspects of value creation” (The IIRC | Integrated Reporting, 2021). In this sense, an integrated report includes “material information about an organization’s strategy, governance, performance and prospects in a way that reflects the commercial, social and environmental context with which it operates” (IIRC, 2011).

Integrated Reporting Framework

The International Integrated Reporting Council (“the IIRC”) is a not-for-profit organization that “comprises global communities, including business and other reporting entities; providers of financial capital; policy makers, regulators and exchanges; the accounting profession; reporting framework developers and standard setters; civil society; and academia,” whose mission is “to establish integrated reporting and thinking within mainstream business practice as the norm in the public and private sectors” (The IIRC | Integrated Reporting, 2021). The Council is formed by 68 organizations, including the Global Accounting Alliance (GAA), Global Reporting Initiative (GRI), Sustainability Accounting Standards

Board, The Chartered Governance Institute, Transparency International, UN Global Compact, and World Business Council for Sustainable Development (WBCSD), among others, and Prof. Judge Mervyn E. King, promoter of the King Reports, is the Chair Emeritus. The <IR> Framework Panel revises and updates the International <IR> Framework. The IIRC published an updated version of the <IR> Framework, originally published in 2013, in January 2021. In this document, IIRC states that integrated reporting aims to improve quality of information, to promote cohesion in corporate reporting, to enhance accountability, and to support integrated thinking (IIRC, 2021).

The guiding principles to prepare and present and integrated report complying with the <IR> Framework are strategic focus and future orientation, connectivity of information, stakeholder relationships, materiality, conciseness, reliability and completeness, and consistency and comparability (IIRC, 2021, p. 7). When a company wants to follow the <IR> Framework in their integrated reports, they have to include eight content elements: Organizational overview and external environment; Governance; Business model; Risks and opportunities; Strategy and resource allocation; Performance; Outlook; and Basis of presentation. For each of the eight content elements, it is raised the question that the integrated report should answer, as well as the organizational and material aspects to be included, key quantitative information, significant factors, and, in some of them, inputs, outputs, and outcomes.

Unlike other reporting standards, such as the Global Reporting Initiative (GR), International <IR> Framework does not outline specifically what measures to report or how value creation is defined (Dumay et al., 2016). This leads to the use of a non-exhaustive variety of key performance indicators (KPIs), adding information about the how, especially through descriptions and processes. Finally, IIRC makes it clear that companies should avoid the use of its label integrated report on those reports that have not been prepared complying with the International <IR> Framework.

Integrated Reporting in Literature

The evolution of the study of integrated reporting in literature coincides, as expected, with the release of the framework by the IIRC in 2013. A search on the Web of Science Core Collection returns 672 results (503 articles) with the concept “integrated reporting” in the topic and 371 results (276 articles) with the concept in the title. Despite the fact that production practically begins in 2013, some papers before already talk about integrated reporting. The first article available, in the healthcare environment, introduces “joint, not marginal, reporting” to improve decision-making (Gore, 1988), but it is not until 2011 when integrated reporting begins to be considered as a new reporting paradigm (Adams & Simnett, 2011). Figure 1 shows the evolution of papers in Web of Science Core Collection with the following search criteria (June, 2021): “integrated reporting,” filtered by articles. The productive peak occurs in 2019, which may pose a change in the trend in the analysis of integrated reporting and justifies the need for alignment toward a comprehensive global system for corporate disclosure, which will be discussed later.

The journal *Meditari Accountancy Research* is focused on the social impacts of accounting, sustainability accounting, CSR, and integrated reporting and leads the ranking of journals followed by *Sustainability* (28 papers), *Journal of Intellectual Capital* (27), *Accounting Auditing Accountability Journal* (24), and *Business Strategy and the Environment* (24) (Table 1).

The top nine authors who have contributed more articles on IR are Warren Maroun, John Dumay, Nicola Raimo, Filippo Vitolla, Charl de Villiers, Michele Rubino, and Madalina Dumitru (Table 2). Not surprisingly, the most prolific authors come from a South African university, the origin of the King Reports, and from where their various case studies are applied (Atkins & Maroun, 2015; van Zijl et al., 2017).

The last systematic literature review by Soriya and Rastogi (2021) evaluates 110 articles and categorizes 5 focus areas: concept of integrated reporting (23% of articles); implementation of integrated reporting (30%); determinants of

integrated reporting (19%); value relevance of integrated reporting (14%); and sustainability and integrated reporting (15%). The area of concept of integrated reporting focuses on theories given by researchers (namely, signaling theory, stakeholder theory, legitimacy theory, and agency theory) to elucidate the framework of IR (Soriya & Rastogi, 2021). The area of implementation of integrated reporting focuses on the connection between business strategy and sustainability, as well as communication. In this area, comparative studies such as that of Tjahjadi et al. (2020) predominate. The area of the determinants of integrated reporting is the most productive and also the most practical when entering into the

relationship with quality (Barth et al., 2017; Cooray, Gunaratne, & Senaratne, 2020; Cortesi & Vena, 2019; Cosmulese et al., 2019; Demartini & Trucco, 2017; Gerwanski et al., 2019; Malola & Maroun, 2019; Mans-Kemp & van der Lugt, 2020; Pistoni et al., 2018; Vitolla et al., 2019b). In this sense, this line of research has two aspects: the first one analyzes the determinants of IR adoption, and the other one analyzes the determinants of IR quality. Vitolla et al. (2019b) reviewed the determinants of integrated reporting and summarizes tested hypotheses from 13 authors: mainly being classified in corporate governance variables, country-level variables, and corporate variables. A summary of their results (only for IR adoption and IR quality) can be found in Table 3.

Integrated Reporting, Table 3 Literature review summary. (Source: Vitolla et al. (2019a pp. 1594))

Dependent variable	Authors	Tested hypotheses	Main findings
IR adoption	Frias-Aceituno et al., (2013a, 2013b, 2014); Garcia-Sanchez et al., (2013); Lai et al., (2016); Sierra-Garcia et al., (2015)	Firm size (+), firm profitability (+), business sector (+), industry concentration (–), growth opportunities (+), ESG disclosure rating (+), financial leverage (+), environmental sensitive industry (+), CSR report assurance (+), IR assurance (+), board size (+), board independence (+), board activity (+), board national diversity (+), board gender diversity (+), board average age (+), civil law countries (+), strictly enforced regulation (+), power distance (–), individualism vs. collectivism (–), masculinity vs. femininity (–), uncertainty avoidance (+), long-term vs. short-term orientation (+)	Firm size (+), firm profitability (+), industry concentration (–), ESG disclosure rating (+), CSR report assurance (+), board size (+), board gender diversity (+), civil law countries (+), strictly enforced regulations (+), individualism vs. collectivism (–), masculinity vs. femininity (–)
IR quality	Gerwanski et al., (2019); Vitolla et al., (2019b)	Learning effects (+), readability (+), gender diversity (+), assurance (+), DJSI (+), earnings management (+), power distance (–), individualism vs. collectivism (–), masculinity vs. femininity (–), uncertainty avoidance (+), long-term vs. short-term orientation (+), indulgence vs. restraint (–)	Learning effects (+), gender diversity (+), assurance (+)

The area of value relevance of integrated reporting analyzes, on the contrary, the effects of practices IR in terms of asymmetry of information, firm valuation, or cost of capital. These effects, however, are usually related not so much to the integration of information but to the mere disclosure of reliable and quality information (Cooray, Senaratne, et al., 2020) Finally, the area of sustainability and integrated reporting reflects on how reporting systems secure trust and reduce opacity in organizations (Chaidali & Jones, 2017; Dumay et al., 2019).

Key Issues and Future Directions

Among the future challenges in relation to integrated reporting, Dumay et al. (2016) highlight

the disconnection between IR research and IR practice, detecting the need for a more interventionist research, helping organizations to land theoretical concepts proposed by the IR framework. This is related to the main risk that integrated reporting has considering the <IR> Framework, which is that it does not involve a substantial change in corporate culture and that it remains a formal tool (Higgins et al., 2019; Vitolla et al., 2019a). For this reason, the need for an increase in case studies, something also proposed by Soriya and Rastogi (2021), and the stakeholder pressure set up as vigilantes to enhance the quality of reports and seek that qualitative leap to true integrated thinking. However, the convenience of the exclusive use of the concept of integrated reporting should be considered, especially with regard to how it may affect stakeholders'

understanding and trust (Beck et al., 2017). Following this line, it is necessary to investigate not so much the determinants of integrated reporting but the perceptions of stakeholders from a broader perspective, in line with what is proposed by Stubbs et al. (2014).

Although del Baldo (2015) wondered whether it was time for integrated reporting in SME in 2015, the truth is that there is also a lack of case studies in non-listed companies, something from which they could benefit when planning and understanding their strategy and their risk management. The next steps in IR would have to go hand in hand with experimentation, so that they carry out comparative studies with other types of approaches, as well as propose industry-based guidelines in line with the experience of other initiatives.

Finally, Soriya and Rastogi (2021) also detected the need for harmonization of financial and non-financial standard. Precisely, this need for harmonization has been reflected in the shared vision announced in September 2020 by five of the leading framework and standard-setting organizations (CDP, CDSB, GRI, IIRC, and SASB). After establishing the different definitions of materiality proposed by the standards, they acknowledge that there is substantial work to consolidate the technical content and reflect the different bilateral efforts that have already been carried out (SASB and CDSB; GRI and IIRC; GRI and SASB). Knowing how to understand these formal collaborations, assuming their commitment in favor of a joint market guidance, will favor the implementation by all types of organizations of integrated reporting systems, which in turn benefit the ultimate recipients of information.

Summary

The evolution of the study of integrated reporting in literature explodes with the release of the framework by the IIRC in 2013, reflecting a formalization of processes to promote integrated thinking and consequently, integrated thinking. However, several authors

highlight the disconnection between IR research (whose main areas are concept, implementation, determinants, value relevance, and sustainability) and IR practice, detecting the need for a more interventionist research. The need for an increase in case studies, not only in listed companies but also in not-listed companies and SME, seeks the qualitative leap to true integrated thinking.

Integrated Reporting for Sustainability

Mara Del Baldo 

Department of Economics, Society and Politics,
University of Urbino Carlo Bo, Urbino, Italy

Synonyms

Business integrated reporting; Multidimensional company reporting; Non-financial reporting

Definition

Integrated reporting (IR) is “a process founded on integrated thinking that results in a periodic integrated report by an organisation about value creation over time and related communications regarding aspects of value creation” (IIRC 2013, p. 7). IR presents a clear and succinct representation of how an organization generates value over the short, medium, and long term. The integrated report corresponds to the outcome of a process that aims to describe how and why an organization has created and will continue creating value

(Girella et al. 2019). Therefore, this voluntary disclosure encompasses both financial and non-financial information that typically concerns environmental, social, and governance issues.

Introduction

IR indicates a significant step in the advancement of corporate reporting and financial accounting by incorporating social and environmental responsibility (Eccles and Serafeim 2011; De Villiers et al. 2020). The IR framework has been made available by the IIRC (International Integrated Reporting Council), an international coalition of companies, institutions, audit firms, investment funds, banks, NGOs, and academics that was set up in 2010 with the vision to align capital allocation and corporate behavior to broader goals of financial solidity and sustainable development through the cycle of integrated reporting and thinking.

IR depends on the voluntary integration of financial and sustainability information – increasingly regarded as value relevant – to better meet investors' expectations and, more generally, stakeholders' needs. It rests on the notion of business viability and sustainability and aims to drive organizational change toward more sustainable outcomes. IR points out the connections between inputs, outputs, and outcomes, as well as between an organization's strategy and its performance. It helps businesses to take more sustainable decisions and helps stakeholders understand how an organization is performing (Stubbs and Higgins 2014).

IR's fundamental concepts are the “six capitals” (financial, manufactured, natural, human, intellectual/organizational, social capital and relationship), the business model, value creation over time, and the principle of integrated thinking.

Capitals are designed as stores of value that can be decreased, increased, or transformed through the company's activities that enhance, modify, or destroy them.

The business model represents the particular system an organization opts for to transform inputs into outputs and outcomes through its

activities, which are carried out to fulfill its strategic plans.

Value creation is contingent on the organization's ability to serve the interests of, and work with, stakeholders (employees, suppliers, customers, partners, local communities, regulators, and policymakers) as well as the ability to manage an extensive range of activities, interactions, and relationships.

Integrated thinking represents an organization's active consideration of the interrelation between its various operating and functional components and the capitals that the organization implements or influences. "Understanding the consequences and implications of decisions across the organisation's important capitals can be described as integrated thinking" (IRCSA 2014, p. 3).

The IIRC argues that integrated reporting "brings together material information about an organisation's strategy, governance, performance and prospects in a way that reflects the commercial, social and environmental context within which it operates" (IIRC 2013, p. 3). Accordingly, an integrated report recounts the organization's complete story, disclosing what drives its value, thus permitting stakeholders to assess its ability to create value from a long-term perspective. It expedites the connection between the management of several types of resources (physical, financial, and intangible assets, such as social and intellectual capital) and joins environmental, social, and governance parameters and key quantitative and qualitative performance and risk indicators (KPIs and KRIs).

Key Issues

The academic, managerial, and institutional world advocate for a more holistic approach to corporate reporting that permits companies to disclose tangible and intangible factors supporting their ability to create value. Several studies have highlighted the inadequacy of traditional systems of financial reporting to illustrate the multidimensional performances of companies and manage stakeholders' needs and

demand for transparency. Moreover, many concrete examples worldwide have demonstrated the unsuccessful attempts of international accounting and financial standards to ensure the reliability of companies' reports. The need to assess and account for the effects produced by corporate management on non-financial performance has been increasingly underpinned by stakeholders' views. Financial reporting does not provide for a systemic vision of a company's value and yields a limited contribution in favoring judgment on resources that determine prospects of future performance, for example, intangible resources that are becoming progressively relevant to investors. Even if precise financial information continues to be of fundamental importance, many companies do not disclose their intangible assets in the balance sheet. Relative to such critical features, the IR approach assures that it is "holistic, strategic, responsive, material and relevant across multiple time frames" (Adams and Simnett 2011, p. 292).

IR principles are appurtenant no matter the size and the private, public, or not-for-profit nature of the companies. In recent years small-to medium-sized enterprises (SMEs) have also begun to implement this emerging model of corporate reporting (Del Baldo 2017). Correspondingly, an "ad hoc" guideline has recently been released, addressing their specific attributes (NIBR 2018). Both public policy and organizational practices in this area have grown posthaste, attracting considerable academic attention (Dumay et al. 2016).

On the one hand, among the research on the rationale of IR, the institutional and stakeholder theory have been put into practice to identify the external and internal factors that drive an organization's decision to implement IR. Stakeholder theory has been used to understand why organizations decide to divulge their value process in regard to stakeholders' expectations (Haller and van Staden 2014). Amid the internal factors, we can confirm that size and gender diversity positively correlate with IR adoption (Garcia-Sánchez et al. 2013).

Institutional theory has been used to investigate country-level determinants (i.e., political

systems cultural characteristics, and economic development) and company-level features (i.e., the economic sector or company size) that drive organizations to disclose the company's value by implementing the IR (Frias-Aceituno et al. 2014). Companies headquartered in market-based economies or Civil Law countries appear more likely to introduce IR because of more stakeholders' pressure and/or law enforcement mechanisms influencing disclosure (Vaz et al. 2016). At the organizational level (micro-level) various mechanisms influence whether organizations implement IR or not: normative mechanisms (based on non-imposed values), coercive norms, and mimetic pressure. The latter factor is due to the fact that companies are prone to imitate the behavior of best practices and/or competitors (Jensen and Berg 2012).

On the other hand, research on "how" IR users put this new approach into practice should be further refined to understand whether IR motivates innovative disclosure mechanisms and organizational changes regarding processes and structures, "forcing" companies toward sustainability by taking another look at their business model (De Villiers et al. 2014). However, there are conflicting interpretative positions. Some scholars highlight that sustainability reporting acts more productively as a catalyst for change while others affirm that IR is used to drive change because it is oriented toward the future and attempts to capture interconnections between the financial and non-financial drivers of performance, thus resulting in a fundamental shift in how managers consider strategy and value creation and communicate with stakeholders.

However, IR has been condemned for its prevailing focus on financial capital and investors. Moreover, it has been maintained that IR implementation insists that companies devote a great deal of resources with regard to time, human and financial resources. Ultimately, questions have been put forward on the assurance aspects of IR, calling for frameworks and for regulatory bodies to alter their auditing standards (Cheng et al. 2014).

Summary

IR has prompted a challenge that unfolds new frontiers for both academic research and business applications (Eccles and Krzus 2010; Adams 2015) and enhances the transition to new processes of communication and stakeholders' management. The necessity to assess, monitor, and communicate traditional (economic and financial) and ESG – governance, ethical, social, and environmental – performance underpins the expansion of new accounting and accountability tools and processes like integrated reporting that help companies better understand whether responsible and sustainability-oriented practices are contributing to the enhancement and disclosure of intangible resources. In this regard, the IIRC has devised a holistic approach that draws attention to the way a company creates value. Companies have demonstrated a growing interest in adopting IR to integrate the outcomes of intangible and tangible resource management within their reports, thus prompting IR developments both in theory and practice.

Integrated Sustainability

► Embedded Sustainability

Integrated Value

Lars Moratis

Synonyms

Corporate social responsibility; Sustainable business; Values dividend

Definition

Integrated value is a conceptual systemic approach toward sustainable business developed by Wayne Visser. The concept builds on a myriad of seminal contributions in the field of sustainable business, notably multi-capital approaches. It rethinks how value in society is conceived of and measured and aims to serve as a model for understanding and guiding more comprehensive approaches toward sustainable business. A defining characteristic of the concept of integrated value is that it takes a systems approach, which is identified as the key missing ingredient compared to other conceptualizations of sustainable business and, in fact, as an explanation for the lack of impact of sustainable business in terms of addressing society's most pressing challenges in an effective way.

The Failure of Corporate Social Responsibility

One should only have a quick look at the Sustainable Development Goals to realize that our world is facing many severe problems in the ecological and social domain. Among these problems are those of climate change, biodiversity, eradicating poverty, and gender equality. In fact, many of these problems have worsened over the past decades, and research shows that this trend has so far not reversed (Wackernagel et al. 2019).

Against the background of the growth of business attention for sustainability, usually

under the guise of corporate social responsibility (CSR), perhaps one might have not have expected these problems to disappear, but at least to have become less grave in the course of the past two decades. Corporate practices, including adopting sustainability-oriented management standards, developing and implementing CSR strategies, establishing executive pay schemes to reward sustainability performance, and reporting on the results of these practices, have not led to the anticipated results. Since the opposite of these sustainability problems disappearing is the case, this suggests that there is a disconnect between companies' efforts and initiatives in the domain of CSR on the one hand and the impact of these efforts and initiatives on the other.

Visser (2011) provides three reasons for this disconnect. First, CSR is peripheral in nature, meaning that many of the CSR initiatives and projects of companies are not linked to their core business and that management responsibility for CSR oftentimes is located in the marketing and communications department. This means that CSR is usually not part of the core processes of value creation of companies and is at risk of becoming a bolt-on or a plug-in (Moratis et al. 2017). A second reason for the disconnect can be found in the fact that many academic studies of CSR, despite the popular rhetorics around the business value of investing in sustainability, do not show very positive or even a negative economic impact of CSR for companies. In practice, companies also see themselves confronted with markets and organizations that are oriented toward the short-term, encouraging companies to externalize costs to society instead of rewarding sustainability-related initiatives. Third, Visser argues that CSR has been encapsulated by the tyranny of incremental thinking, whereas more radical solutions (e.g., reinventing the business model) are required in order for companies to become a true force for positive societal change and be the driving force of sustainable transformation. In conclusion, approaches toward sustainable business as they have been taken by companies are misguided, and Visser consequently proposes a new conceptualization of CSR, which he labels CSR 2.0.

CSR 2.0 revolves around the idea of counter-ing the reasons behind the disconnect between business CSR efforts on the one hand and developing a more comprehensive and systemic approach toward sustainable business on the other. Five principles are at the core of Visser's idea of CSR 2.0: creativity (applying innovative ideas to societal problems), scalability (moving CSR beyond the boundaries of the firm), responsiveness (meaning adapting to change and practicing accountability), glocality (suggesting that CSR oftentimes manifests itself as (geographical) dilemmas), and circularity (recognizing the inherent limits of Earth's natural systems). Hence CSR 2.0 presents a more holistic approach to modeling business-society relations in which value creation, stakeholder orientation, and an ecosystems approach take central stage.

From CSR 2.0 to Integrated Value

As a next step in conceptualizing the relationship between business and society, Visser proposes the concept of integrated value (IV) (Visser 2017). The term "integrated value" was first coined in a paper by Visser and Kymal (2015) and takes a multi-capital perspective toward sustainability, integrating financial and nonfinancial capital into one framework. While the IV concept builds on CSR 2.0, it should not be seen as an incremental change in conceptualization nor an extension of Porter and Kramer's Creating Shared Value concept (Porter and Kramer 2011), but rather as an entirely new model that demonstrates an entirely new approach toward sustainable business. (Note that in more recent versions, Visser has been substituting the label of integrated value with that of values dividend, emphasizing the positive financial business outcomes of value-driven business.)

IV takes a far more systemic approach than CSR 2.0, building on a myriad of seminal contributions in the field of sustainable business on the hand, including Ekins (1992) and Hart and Milstein (2003), and systems thinking and complexity theory on the other, including Von Bertalanffy (1968) and Gleick (1987). This is a defining characteristic of the concept of IV that it takes a systems approach, which is identified as

the key missing ingredient compared to other conceptualizations of sustainable business and, in fact, as an explanation for the lack of impact of sustainable business in terms of addressing society's most pressing challenges in an effective way. Informed by these theoretical underpinnings, it sets out to conceptualize sustainable business through recognizing the interconnectedness of economic, technological, human, social, and ecological systems. In doing so, Visser's aim is to rethink how value in society is conceived of and measured, and IV serves as a model for understanding and guiding more comprehensive approaches toward sustainable business.

In order to weave together academic literature, society's most pressing challenges and the roles and responsibilities of business into the IV concept, Visser distinguishes between five forces of systemic breakdown or fragmentation that reflects global sustainability challenges and five forces for integration, reflecting innovative solutions to the global problems driven by companies. The five forces of fragmentation include disruption (any instability that threatens human life, safety, and security), disconnection (any form of isolation that prevents human communication and effective data sharing), disparity (any inequities that increase social friction or inefficient resource utilization), destruction (any production and consumption that leads to the decline of resources and disruption of ecosystems), and discontent (all unhealthy lifestyles and toxic environments that impair human well-being). The five forces of integration that counter the fragmentation include innovations that are secure (lowering risk, aiding recovery, and ensuring continuity), smart (connecting people and things, using big data, and artificial intelligence), shared (equity, inclusive design, and sharing platforms), sustainable (bioproducts (biological/organic, bio-based, biodegradable, and biomimicry-inspired), zero waste design and being climate positive through carbon productivity), and satisfying (promoting human health and improving meaning in work).

While many multi-capital perspectives are merely used as part of methodologies that measure the impact of business in the various sustainability domains, Visser notes that IV is

“focused on how value is being created from innovative solutions that are secure, smart, shared, sustainable, and satisfying. IV, hence, emphasizes the need to create synergies between the forces of integration. As Visser notes (2017, p. 13), sustainable transformation can only be achieved through the synergistic approach of integrated value.

Summary

This chapter deals with the concept of integrated value, as proposed by Wayne Visser. Taking a systems approach toward sustainability, this concept relies on a multi-capital perspective and can be seen as an explanation for the lack of impact of current approaches toward sustainability in general and sustainable business in particular.

Integrity

Jellie Molino
University of Turin, Turin, Italy

Synonyms

[Honesty](#); [Probity](#); [Uprightness](#)

Definition

The term integrity means soundness of moral principle and character. It includes but is not limited to probity, impartiality, fairness, honesty, and truthfulness.

Integrity is often associated with the qualifications of public officers and/or the fidelity and honesty in the discharge of official duties. The concept of integrity, together with transparency and accountability, has been identified by the United Nations countries as part of the founding principles of public administration (Armstrong 2005). Article 101 of the UN Charter specifically requires the “highest standards of efficiency, competence and integrity” in UN employment, a requirement that has been adopted by many Member States.

Introduction

The most recent instrument on the importance of integrity in public service is the 2017 Organization for Economic Cooperation and Development (OECD) Recommendation on Public Integrity. It defines public integrity as a consistent alignment

of, and adherence to, shared ethical values, principles, and norms for upholding and prioritizing the public interests over private interests in the public sector. As one of the key pillars of political, economic, and social structures, which is essential to the economic and social well-being and prosperity of individuals and societies as a whole, public integrity can be a strategic and sustainable response to corruption. OECD identifies corruption as the cause for inequality, exclusion, and disillusionment and highlights the importance of integrity in promoting prosperity.

Integrity as a tool against corruption is not a new concept. In fact, as early as 2008, OECD has already recommended 10 principles in enhancing integrity, more particularly in public procurement, (see for example, William, 2002 on the review of the OECD initiatives in fighting corruption from 1994 to 2006). Accordingly, integrity has been identified as one of the three pillars in public procurement; the two others are competition and transparency.

In the U.S. federal procurement, for example, the word “integrity” is often used to describe rules of conduct for procurement personnel in the government and private industry, “Government business shall be conducted in a manner above reproach and . . . with complete impartiality and with preferential treatment for none. Transactions relating to the expenditure of public funds require the highest degree of public trust and an impeccable standard of conduct. The general rule is to avoid strictly any conflict of interest or even the appearance of a conflict of interest in Government-contractor relationships. While many Federal laws and regulations place restrictions on the actions of Government personnel, their official conduct must, in addition, be such that they would have no reluctance to make a full public disclosure of their actions.” (cited in Schooner 2002).

Measures to Ensure Integrity in Public Procurement

Traditional approaches in enhancing integrity in public procurement include increasing competition,

promoting transparency, providing adequate oversight methods, and enforcing sanctions (Allen 2002). While the 10 OECD principles in public procurement overlap in the nature of their importance, they can be simplified according to the means by which they can be used as a measure to ensure integrity in public procurement, to wit:

- Increasing competition: Principle 2 on competitive tendering; Principle 5 on preventing risks to integrity in public procurement
- Promoting transparency: Principle 1 on the provision of transparency in the public procurement cycle; Principle 6 on cooperation between government and the public sector to maintain high standards of integrity, especially in contract management; Principle 10 on empowering civil society, the media, and the general public to scrutinize public procurement
- Providing adequate oversight methods: Principle 3 on ensuring that public funds are used in public procurement for their required purpose; Principle 4 on ensuring that procurement officials meet high standards of knowledge, skill, and integrity; Principle 7 on providing specific mechanism to monitor public procurement and detect misconduct and apply sanctions
- Enforcing sanctions: Principle 8 on establishing clear chain of responsibility with effective control mechanisms and Principle 9 on the provision of an effective remedies systems

Moving Forward

Traditional approaches in promoting integrity are, more often than, highly focused in preventing corruption; hence, most of the measures that have been implemented are dependent on stricter compliance and tougher enforcement.

Integrity, however, is more than fighting corruption. The people, both public and private, expect nothing less than service with fairness and efficient management of public resources. Integrity, therefore, has become a prerequisite to

public trust which is a keystone of good governance (Diaz 2017).

More than implementing executive, legislative, or even judicial acts in curbing corruption, there is a need for a collective action from the government, the private sectors, civil societies, and individuals across jurisdictional borders.

In public procurement, for instance, the principle of integrity should have a wider significance other than combating corruption. An ethical procurement is not limited to a procurement that is free of corruption but must also be free of fraud and unsolved conflicts of interests. Compliance, therefore, with code of public ethics should be the primordial measure in promoting integrity across sectors and regardless of jurisdiction.

Company culture; Compliance management; Corporate integrity; Ethical behavior; Integrity culture; Moral behavior

Definition

Established compliance management systems are not sufficient to guarantee that employees act in a law-abiding and ethical manner. In fact, modern compliance management systems rather require complementary initiatives such as an integrity management which expands the focus which is often only limited to legal content, by considering business decisions also from a moral, social, societal, and ecological perspective. The goal of integrity management is not simply having employees strictly following the rules, but instead promoting moral conduct. Therefore, integrity management particularly pays attention to the ethical behavior of the individual employee, as well as the company and management culture. The company culture can be understood as the sum of the organization's collective values, convictions, attitudes, and mindsets. The authors point out possibilities and limitation on how companies can influence their culture by setting up targets, incentive and sanctions schemes, in addition to the already-existing control measures.

Introduction

Integrity management is an extension of classic (legal) compliance. It broadens the focus of compliance, often limited only to legal content, by

including questions that may be relevant to companies from a moral perspective. The risk of breaking laws and regulations is no longer only evaluated from a legal and financial point of view but is expanded by moral, social, societal, and ecological perspectives. At the same time, this requires the management to become more attentive and sensitive to these issues. The additional content and perspectives of integrity management lead to a conscious expansion of corporate responsibility beyond legal guidelines by including challenges and stakeholder groups, which have not been considered yet. The moral stipulation in integrity management states that a company's business activities must always take other stakeholders and their interests into account as well as not harming these in any way. This applies to both, the company's own value chain as well as to the upstream and downstream value chain. However, it must be feasible and within reason for companies to assume this responsibility. An organization's striving for integrity should therefore not be called into question if it is not possible for the company to comply with ethical obligations or only possible with an extraordinarily large investment in time and energy. On the other hand, making ethical demands of companies in terms of their business activity is legitimate, in so far as fulfilling these requirements is in principle possible and within reason.

In addition to being sensitive and attentive to compliance and ethical issues, establishing corporate integrity demands, above all else, the organization, management, and employees to *act* in a corresponding manner is needed. This requires that the company's personnel accepts and acknowledges the "correctness" of the values and principles. The personnel should be able (or be enabled) to analyze alternative courses of action autonomously and based on personal reflection. The challenge of getting personnel to act according to values and principles arises especially in situations in which these behavioral axioms come into conflict with a company's other goals (such as making profits). The corporate integrity and the moral fortitude of an organization become particularly visible in these dilemma situations and are characterized by the

fact that the outcome of the situation reflects the values and principles in the best possible manner. However, integrity does not mean that this outcome is automatically achieved simply by personnel obeying numerous company rules and guidelines without question. It is not possible to regulate every single action or decision situation. This means that rules and regulations have their limits, particularly in gray areas and dilemma situations. The major difference between classic compliance management and integrity management is that the latter is not solely based on a set of rules, but far more driven by the actors taking personal responsibility for their actions, as well as a value-based company and management culture (Wieland 2012, p. 36). In this sense, the employees and management need to be empowered to recognize the relevant moral questions in their work areas and, together with internal stakeholders, to evaluate and make decisions of integrity accessible (Wieland 2014, p. 15ff). The goal of integrity management is not simply having employees strictly following the rules, but instead promoting ethical conduct. The personal accountability of employees and management is one of the core elements of integrity management and should encourage and empower the actors to use and follow existing rules in dilemma situations, while at the same time not lose sight of business interests. How can companies reconcile running a successful and efficient business while simultaneously following ethical principles and legal regulations? This is the central question we must use as an orientation. The overriding principle, of course, cannot be to avoid all compliance risk by refraining from business activities. Nevertheless, in individual cases, it can be necessary to completely abandon a business deal. In this context, it is important to regularly question existing guidelines and policies and procedures in terms of their purpose, their necessity, and meaningfulness – especially as it is well-known that not all company rules are equally relevant, and some are even unnecessary. Last but not least, compliance often has a negative reputation in many companies because of the unnecessary or ineffective regulations and the resulting superfluous bureaucracy.

Integrity management confronts this challenge using an argumentative procedure: by reflecting the meaning and purpose of rules and laws as well as the values and norms embedded therein. This results in “good reasons” for complying with regulations. Regarding the effectiveness of rules and their compliance, there is certainly a difference between organizations that demand compliance “for compliance sake” and thus implement a “compliance to avoid liability” strategy and organizations where the purpose of compliance activities is legal compliance and the internalization of (moral) values. In the latter case, e.g., illegal payments to secure a deal are simply not tolerated by the company. Such an integrity management approach can thus also contribute to an increased effectiveness and credibility of existing rules and compliance as a whole.

Compliance and Integrity Culture

The Socialization of Employees

Compliance management, as it is normally practiced, places structural aspects such as rules, business processes, and internal controls in the foreground, whereas integrity management specifically focuses on factors related to the company culture. The culture of an organization and its influence on employees not only represent the primary driving force, but at the same time is also the biggest challenge in implementing corporate integrity.

Company culture can be understood as the sum of the organization’s collective values, convictions, attitudes, and mindsets (Janke 2015, p. 96; Schönborn 2014, p. 280) and is, in the end, a reflection of the truly accepted and practiced principles (Martin et al. 2014, p. 298). In an ideal case, these are identical to the principles listed in the code of conduct or the codified norms and values in the company’s guidelines. However, simply putting these principles down in written form does not create a company culture of integrity, nor does it ensure that they are internalized by employees.

The company structure and the company culture are equally important starting points for

effectively preventing unethical behavior because both elements affect employee behavior. Employees pick up information regarding appropriate and prohibited behavior from structural measures such as rules, controls as well as incentive and sanction schemes. Yet, behavioral expectations are communicated in a significantly more nuanced manner via the company culture or the general work environment (Treviño et al. 1998, p. 457f, 463f).

The influence of colleagues and management on individual behavior is considerable as employees spend a large part of their social lives in companies (Jones and Ryan 1998, p. 437). The social environment or rather the corresponding reference group (the company as a whole, particular departments, or actors) thus has a strong influence on the behavior of an individual (Jones and Ryan 1998, p. 435ff) and serves as model for learning socially accepted norms and behaviors (Bandura 1971). Adapting and assimilating (un)ethical behavior from the social environment is motivated by the human need for social acceptance (Cohen and Morse 2014, p. 48), so that individuals specifically tend to take on behaviors that are “socially acceptable,” regardless of whether these are considered “ethical” or “unethical” outside the reference group.

According to classic social-learning theory (Bandura 1971), there are two essential learning mechanisms, on the basis of which individuals learn socially accepted behavior. On the one hand, individuals receive positive and negative *feedback regarding their behavior* over time from their social environment. They thus learn to reproduce behaviors that receive positive reinforcement and avoid negative reinforcement. On the other hand, individuals make inferences about acceptable behavior by observing the *behavior of others*. People experience which behaviors have social incentives and which are sanctioned, without having displayed the specific behavior themselves (Bandura 1971, p. 3ff; Jones and Ryan 1998, p. 435ff). The following applies: The more people display a specific behavior, the more valid and convincing this behavior appears to be for the individual. The behavior of the social environment, whether active behavior or inaction, is

seen as the measure of “moral” behavior in the eyes of the actor (Moore and Gino 2013, p. 56f).

In a business context, this means that, as a rule, workers take their cues from the environment. According to the theory, management and colleagues are the most important orientation points for the individual employee (Mayer et al. 2013, p. 89. 92ff). The expected behaviors are derived from the “normal customs” in the company (Jones and Ryan 1998, p. 437). The company environment has a concrete influence on the way specific issues and situations are interpreted, the focus of employees, and the decisions and behaviors that seem to be appropriate (Umphress and Bingham 2011, p. 629).

The specific cultural or social setting determines which strategies and behaviors are classified as “correct” or “incorrect.” This, however, also means that employees – exposed to an unethical subculture within the company – will act according to the “group morals.” Subcultures in companies develop independently from the rest of the organization, e.g., based on spatial, functional, or communicative distance. They can establish their own value system as well as behavioral expectations that are characterized either by the active promotion of implicit assumptions or by the rewarding of immoral behaviors (Umphress and Bingham 2011, p. 629).

Due to the fact that employees tend to display behaviors that are rewarded or incentivized by the company or their reference group (Jones and Ryan 1998, p. 436), a “prefabricated” organizational framework with its own rules, incentive, and sanction schemes can motivate individuals to refrain from their own considerations when faced with moral dilemmas and challenges (Martin et al. 2014, p. 309f). This makes it even more important to have an integral organizational framework with credible principles that are reflected in structural measures. An integrity management system that motivates management and employees to take more personal responsibility can support the creation of these framework conditions.

In order to better understand the factors that influence the “socialization” of employees and the “pulse of the organization,” it can be helpful to conduct an “integrity survey” when developing an

integrity strategy (Grüniger and Schöttl 2017, p. 10ff). A survey facilitates the analysis of the personnel's actual perception and at the same time facilitates the implementation of the organization's norms and values and those aligned with the stakeholder's expectations. Moreover, integrity surveys allow to make inferences about what is good and effective in the existing compliance measures as well as gain insights into how the behavior of management and employees is perceived. As a result, targeted measures to adjust the existing (compliance) structures can be designed and implemented, which, at the same time, makes it easier to communicate the company's values and standards.

Company and Employee Identification

When employees strongly identify with their company, this can contribute to the adoption of norms and values and the prevention of unethical behavior (Moore and Gino 2013, p. 62). The prerequisite for employees identifying with the company is a shared understanding of norms and values. The concept of corporate identity, as a whole, is described as "an effective strategy to prevent criminal activity" (Bussmann 2004, p. 42), due to the fact that "a strong emotional and social attachment to the company [...] guarantees a certain protection against individuals negatively impacting their own company[.]" (Bussmann 2004, p. 42). This identification creates a connection between the organization and its personnel (Schönborn 2014, p. 278) which further triggers a personal feeling of obligation for the company's success or failure, so that the personnel feels responsible for preventing the organization from any harm (Eigenstetter und Löhr 2008, p. 21; Janke 2015, p. 274; Palazzo 2001, p. 53). Empirical studies confirm a negative correlation between employee commitment and behavior that negatively impacts the company (Martin and Cullen 2006, p. 185). A lack of identification with the company can additionally make it easier for the delinquent to justify white-collar crime and unethical activity (Brinkmann 2007, p. 158).

Nevertheless, it is important not only to focus on the favorable elements of strong employee identification. There is simultaneously the

potential that a double standard can develop in which negatively impacting third parties in favor of one's own company is accepted or even desired (Bussmann 2004, p. 43). Unethical activities are carried out in order to benefit the company, while simultaneously violating personal principles and values (Umpheers et al. 2010, p. 770).

In addition to the organization as a whole, individual groups and subcultures within the company can become reference points for moral conduct. As mentioned above, the human need for belonging plays a role in leading the individual actors to call up group and individual behavior patterns (Ashforth and Anand 2003, p. 10; Moore and Gino 2013, p. 62). The moral norms and values that normally apply to an individual may be suppressed in this context, in favor of affiliated persons and groups (Rorty 1997, p. 141). Strong employee identification can counteract the emergence by such subcultures and their criminal potential, while promoting the creation of a shared understanding of moral values and a sustainable corporate integrity.

Organizational Factors That Influence Company Culture

The natural socialization of employees in the context of the company environment has considerable influence upon their decisions and behaviors. A strong identification with the company can reinforce this effect even more. However, the question remains how the company can influence the culture and its employees' behavior. Based on the findings of "integrity surveys" (Grüniger and Schöttl 2017, p. 10ff; Kaptein 1998, p. 10ff) regarding the status quo in organizations, companies can influence company culture by setting up targets, incentive and sanctions schemes in addition to the already-existing monitoring measures. Moreover, human resource management and instruction, in the form of trainings and workshops, are essential when establishing corporate integrity and implementing integrity management.

Internal Controls

Controls communicate issues the organization considers the most relevant to deal with, in an adequate manner, and therefore are monitored

and/or inspected. In this respect, controls are important instruments used to uncover and prevent white-collar crime and unethical behavior and can, when designed correctly, not only restrict and prevent opportunities for carrying out delinquent behavior, but also act as a deterrent and in consequence as general prevention. Missing or only ineffective controls can on the other hand become an implicit invitation to conduct unethical or criminal activity (Lou and Wang 2009, p. 65; Schuchter 2012, p. 69). Excessive surveillance of employees can however create a negative atmosphere in the company. A culture in which the employees feel observed and where the measures set up by the company to prevent unethical behavior only create mistrust will be counterproductive (Bussmann and Salvenmoser 2006, p. 206; Palazzo 2001, p. 53). Exaggerated controls, which, under some circumstances, even hinder the daily work of employees, could lead individuals to bypass these controls or the bureaucracy that emerges out of these. In general, the use of controls should be limited to important issues and processes and should be well justified to the respective employees.

Goals

Goals and goal agreements fulfill important business functions. They are essential components of human resource management and are regularly monitored and evaluated in order to improve performance. The theory behind the use of goals in companies has been empirically verified and states that workers achieve greater performance when concrete goals are specified (Latham and Locke 1979, p. 70). Studies clearly confirm that setting challenging goals can contribute to achieving maximum performance (Latham and Locke 2006, p. 332f). However, there are also risks in defining goals, particularly in terms of a motivational effect on individuals to act in an unethical manner (Barsky 2008; Niven and Healy 2016, p. 115; Ordóñez et al. 2009; Schweitzer et al. 2004). Goals may therefore not only improve performance but may also increase the tendency to use unethical methods to reach those goals (Ordóñez et al. 2009, p. 7ff). One of the causes of unethical behavior in connection with agreed-

upon goals may be that the goals are often strictly profit-oriented, meaning revenues and profits are the only or most important parameters (Ashforth and Anand 2003, p. 5; Moore and Gino 2013, p. 59). Exclusively focusing on financial goals can divert attention from ethical considerations, because they may encourage actors to focus only on the target to be reached and thereby cause them to disregard potential ethical behavior (Barsky 2008, p. 72; Ordóñez et al. 2009, p. 7f; Moore and Gino 2013, p. 59). As a result, carelessly formulated company and employee goals can contribute to the violation of rules and codices, particularly when the goals do not align with the company's self-defined ideals and principles. Strictly, profit-oriented employee goals may convey the implicit message that reaching the goals is more important than the legal or legitimate means used to do so (Moore and Gino 2013, p. 59).

Setting unrealistic high goals can also have a long-lasting impact on the general level of compliance in a company by putting the affected actors in highly stressful situations and triggering them to use unethical "short cuts" (Ordóñez et al. 2009, p. 9ff; Schweitzer et al. 2004, p. 426ff; Zhang et al. 2014, p. 70). Very few employees would be willing to forego variable salary components or a promotion or, in the long term, even lose their jobs because they did not achieve their goals. The overall pressure to reach the goals set by the company can motivate employees to carry out unethical acts (Jones and Ryan 1998, p. 441).

Unethical behavior cannot of course only be explained by agreed-upon goals. Nevertheless, the potential risk of employees being motivated to reach their goals using dishonest tactics must always be taken into consideration when designing and formulating target schemes (Niven and Healy 2016, p. 125). In the end, the recommendation is to be skeptical of the general effectiveness of concrete goals on employees and not only to make goal agreements dependent on financial parameters. Instead, companies should take the means and measures used to reach those goals into consideration. Thus, realistic and attainable goals are commendable not only in the sense of employee motivation, but also in terms of preventing unethical behavior.

Incentives

The main purpose of using material and non-material incentives in companies is to coordinate and communicate the organization's targets and interests. Incentives are designed to align and focus the personal interests and goals of the employee with those of the company (Frey and Osterloh 1997, p. 308f). A company's incentive system should reward ethically "correct" behavior according to the (ethical) company targets and values, as defined in the code of conduct or code of ethics. In addition, a carelessly designed incentive system (just as goal agreements) poses the danger of implicitly communicating a double standard. If companies communicate norms and values, such as compliance and integrity, but at the same time measure the incentives using only financial parameters, this may give the impression that completing a business deal should be achieved at any price. In this way, "ethical explanations and standards of behavior [...] remain abstract in the day-to-day business at a company and will not be implemented." (Bannenberg 2012, p. 764). Incentives that are solely based on financial success may end up animating employees to only concentrate on the next business deal, which, in case of doubt, can be attained using dishonest business practices.

Such characteristics can quickly become part of the company culture so that unethical behavior becomes acceptable or even upgraded to (implicitly) required behavior, as long as it contributes to reaching the individual's or the company's goals. As long as the company legitimizes and rewards the use of "unethical" tactics to reach goals, no sense of guilt can evolve among the employees (Wieland 2014, p. 78ff). In such cases of double standards, employees are more likely to interpret the proclaimed norms and values as "anti-business measures" (Wieland 2008, p. 162), which are also in conflict with being able to fulfill their own financial interests. Behaving in an unethical manner or making a decision contrary to the company's values and rules, simultaneously supported by the incentive system, can easily be justified on an individual level. Finally, employees will also see the rewards colleagues receive for unethical behavior as evidence that

this is adequate behavior and will orient themselves thus in the future (Umphress et al. 2010, p. 777).

An incentive structure that gives unethical behavior the status of a "social custom" (Bannenberg 2012, p. 764) can lead to the repression of ethical insights and thus facilitate unethical behavior (Cohen and Morse 2014, p. 52). An incentive system based exclusively on key performance indicators increases the danger of overtaxing the moral fortitude of its employees and also fosters the repression of ethical considerations and objections in favor of pursuing personal financial interests.

Sanctions

In addition to incentives, another tool companies use to structurally influence behavior is to consistently impose sanctions for misconduct.

Regardless of whether unethical behavior benefits or harms the company, such behavior requires a clear response from upper management. In the spirit of the "tone from the top" and the "tone from the middle," the credible (and also communicated) commitment of management to integrity and compliance means that unethical behavior and white-collar crime in particular must result in consistent disciplinary action. Undesired behavior that does not lead to appropriate sanctions gives the impression that the company's values and rules are irrelevant and that violating them will be tolerated.

Thus, the effectiveness of measures put in place specifically to avoid unethical behavior depends on incentives and sanctions that promote the "correct" behavior (equivalent to the proclaimed norms and values). Only in this way, seriousness and credibility can be honestly communicated internally and externally and facilitate an effective prevention program (Grüniger 2016, p. 47ff).

Not only is the reputation of the company at stake when upper management reacts to unethical actions in an inconsistent manner and without repercussions, but the company culture can also suffer when management is too lenient or sanctions are used in an uneven manner. A company culture that is perceived as "fair" requires that

employees and management are all treated equally (Galley 2008, p. 116). Especially when management is dealing with a case of unethical behavior, any exaggerated discretion can raise suspicions that something is being hidden and that managers are receiving preferential treatment. This can lead to a feeling of mistrust and frustration among employees, both of which can become motivational factors for unethical behavior and potentially the basis for justifying their own misdeeds (Bussmann 2004, p. 46; Bussmann and Salvenmoser 2006, p. 209; Galley 2008, p. 116).

Certainly, unethical behavior must be punished independent of the perpetrator's position in the hierarchy; however, the focus here is not on establishing a culture of fear. Exaggerated threats, sanctions, and severe punishments can increase the pressure on "practicing" delinquents to such a degree that, from the perpetrator's perspective, "cover-up measures" become increasingly necessary and can lead to an even deeper involvement in criminal activity (Schuchter 2012, p. 211f). As a whole, sanctions, such as incentive systems and goal agreements, must be designed in a moderate and balanced, yet consistent and, most importantly, credible manner, based on the company's values and standards.

Human Resource Management and Training

An additional – and most likely the most important – element in terms of influencing company culture and corporate integrity is the company's management. Managers play a key role in achieving (ethically) adequate behavior (Ashforth and Anand 2003, p. 6; Brown et al. 2005, p. 119): They serve as role models for employees (Brown et al. 2005, p. 119). Both upper management and, particularly, an employee's direct supervisor can play a significant role (Kronawitter 2013, p. 81; Schuchter 2010, p. 83). Management acts as a representative of the company, determining and communicating rules and standards that apply to all personnel. In addition, management is responsible for rewarding exemplary behavior and initiating disciplinary procedures for misconduct. Based on their influence on employees, the management culture of a company is one of the most

essential factors in integrity management and for establishing values and principles in that company. Manager's actions can however also pose dangers to a company culture of integrity. For example, when management makes unclear or ambiguous remarks, fails to pursue, or even praises unethical behavior, this leaves employees leeway in terms of interpreting the priority the company places on values and rules (Thielemann 2005, p. 37). An important task for management in the framework of integrity management is therefore communicating and keeping the employees' focus on the values and principles of the company and the resulting implications for ethical business practices, very much in the sense of the "tone from the top" and the "tone from the middle." Management can contribute to an increase in integrity and compliance by displaying consistent behavior according to company guidelines as well as by clearly communicating targeted norms and values and making them "accessible." By agreeing on balanced goals and setting up a corresponding incentive system, based not only on financial success, but also on the manner in which these goals are reached, management can facilitate employees acting in a compliant way and support a company culture of integrity.

The rules, norms, and values of the company should be conveyed to the employees and managers via trainings and workshops and based on the "pulse of the organization" determined by the integrity surveys. High-quality training modules focusing specifically on management and employees' needs, and in which possible risks, conflicts, and compliance-related dilemmas are dealt with, can contribute to helping all personnel acquire the required integrity competence. The often-used web-based trainings, which employees normally just "click through," are not sufficient.

Department-specific challenges and stakeholder expectations (e.g., R&D, Sales, Purchase, Finance, etc.) can be discussed and dealt with in the framework of so-called "Integrity Conflict Circles." Each of these measures contributes to a high awareness for legal and ethical questions at an individual and organizational level.

Summary

The emissions scandal and the numerous examples of misconduct in the financial sector once again show that the established compliance measures and so-called “best practices” are not sufficient to guarantee that company employees act in a law-abiding and ethical manner. Compliance management systems rather require complementary initiatives such as integrity management, which particularly pays attention to the company culture and management and employee behavior. Moreover, compliance can provide a company with stability via standards, guidelines, and values, which is necessary in a constantly changing business environment and regularly transforming organizational structures (e.g., due to mergers and acquisitions). At the same time, it needs to be kept in mind that the foundation of effective compliance is a company culture of integrity. This recursive correlation between compliance and company culture is apparently still too often neglected. It might be an additional explanation for the numerous corporate scandals that have occurred over the past years, despite existing compliance systems. In addition to the typical structural compliance measures (rules, processes, and controls), the “soft aspects” of leadership and culture (which, in reality are significantly “harder”) need to be taken into consideration. Integrity requires the appropriate behavior on the part of management and a leadership continually demanding as well as facilitating ethical considerations in the day-to-day business. Companies have to enable their employees to recognize and evaluate ethical dilemma situations. This may mean that established behaviors and decision structures have to be questioned and changed. Integrity management can guide and support management and personnel in this process via, for example, tailor-made training modules. By using practical examples and ethical dilemma from everyday business, companies can facilitate a discourse about adequate and desired behaviors. This type of cultural change is, however, a long-term process. Companies, their management, and

employees all require patience as well as the ability and the will to collaboratively deal with conflicts and challenges in a constructive manner.

Integrity management challenges the typically-pursued approach of attaining compliance via strict and blind obedience as well as the use of monitoring and controls. In the face of increasing regulatory density and complexity, unquestioned compliance can quickly become an end in itself, which stifles managers and employees’ potential, creativity, and most of all their ability to think for themselves. In the framework of integrity management, it would appear to make more sense to use a procedure which promotes the actors’ sense of personal responsibility and ability to critically question existing regulations and thus be able to make a reflected decision between two possible courses of action. In this case, employees would follow laws and ethical standards not because of codified norms and the corresponding threat of sanctions, but instead based on a conscious, intrinsic insight into the correctness of the “ethical option.”

Definition

The ongoing intensification of competition in the present global market environment led the emergence of never-ending radical shifts in technology that induced the rise of ever-growing challenges

and uncertainties for firms' survival and growth (Baruah and Ward 2015). As a subfield of entrepreneurship, the concept of intrapreneurship was first coined by Gifford and Elizabeth Pinchot in the late 1970s (Baruah and Ward 2015; Cader and Badulescu 2015; Nielsen et al. 1985). Despite a plethora of research that addressed intrapreneurship, the close association between entrepreneurship and intrapreneurship led the absence of conceptual clarity and the emergence of not only confusions about the nature of intrapreneurship but also controversial definitions of the phenomenon (Menzel et al. 2007; Sharma and Chrisman 1999).

In the pertinent literature, intrapreneurship is investigated substantially through organizational and individual level of analysis. Terms including intrapreneuring (Pinchot 1985), corporate venturing (Vesper 1990), entrepreneurial orientation (Lumpkin and Dess 1996), internal corporate entrepreneurship (Jones and Butler 1992); corporate entrepreneurship (Guth and Ginsberg 1990) have been used to refer to intrapreneurship which reflects the intrapreneurial characteristics of an organization. While corporate entrepreneurship is widely used interchangeably with intrapreneurship (Neessen et al. 2019), some authors assert that they are related but different concepts (Åmo 2010). At organizational level, intrapreneurship reflects broadly "*the entrepreneurial spirit or entrepreneurship within an existing organization*" which reflects "*a process that goes on inside an existing firm, regardless of its size, and leads not only to new business ventures but also to other innovative activities and orientations such as development of new products, services, technologies, administrative techniques, strategies, and competitive postures*" (Antoncic and Hisrich 2001, p. 498). Regarding the individual level of intrapreneurship, it is viewed as the employees with entrepreneurial features within an existing organization (Pinchot 1985). In this sense, scholars underlined the difference between an entrepreneur and intrapreneur by pointing out that intrapreneurs are the agents who realize new ideas by using the resources of an existing organization in which they work (Pinchot and Pellman 1999, Baruah and Ward 2015;

Camelo-Ordaz et al. 2012; Farrukh et al. 2017) while an entrepreneur fosters and realizes an idea by starting a new venture (Gartner et al. 1988). Blanka (2019, p. 551) proposes a definition for intrapreneurship by encompassing the multilevel nature of the construct which is "*intrapreneurship is a process whereby employee(s) recognize and exploit opportunities by being innovative, proactive and taking risks, in order for the organization to create new products, processes and services, initiate self-renewal or venture new businesses to enhance the competitiveness and performance of the organization.*"

Introduction

The accelerating speed of market globalization created an increasingly turbulent and competitive world markets where firms are seeking for ways to innovate to catch up with the revolutionary technological advancements and gain a sustainable competitive advantage (Kuratko and Audretsch 2013). As Schumpeter (1934) pointed out the role of entrepreneurship in innovation and economic developments of the countries, the concept has become the center of attention. In this vein, entrepreneurship has been an aspirational goal for firms to foster innovation and outperform their rivals. Correspondingly, entrepreneurship field has gained momentum through the interest of scholars and practitioners which promoted the comprehensive understanding of not only the role of corporate entrepreneurship and entrepreneurs but also the entrepreneurial spirit that resides in organizational members (Antoncic 2007; Antoncic and Hisrich 2001, 2003; Gawke et al. 2019; Parker 2011; Pinchot 1985). Despite the dispersed conceptualization of intrapreneurship in the existing literature, there are two main levels of analysis that a substantial amount of studies addressed including individual and organizational level intrapreneurship (Blanka 2019; Gawke et al. 2019; Neessen et al. 2019). Therefore, intrapreneurship has been investigated through a multilevel nature.

The concept of intrapreneurship has been under the spotlight of scholars since the late

1970s. Despite the burgeoning interest, there are still controversies on a universally accepted definition of the concept (Blanka 2019; Parker 2011). Besides, since research on this concept is founded on various theoretical grounds, the results are not consistent. For example, while some studies address intrapreneurship at individual level (Gawke et al. 2019; Neessen et al. 2019), others approach it through an organizational level lens (Antoncic and Hisrich 2001). After the inception of the concept, Miller (1983) pointed out an organizational level approach by underlying the extent that a firm's behavior is *innovative, proactive, and risk-taking*, which indicates the entrepreneurial dynamics of a firm, also refers to *entrepreneurial orientation* (Bouchard and Basso 2011; Covin and Lumpkin 2011; Covin and Slevin 1991; Lumpkin and Dess 1996; Miller 2011). This conceptualization of entrepreneurial orientation was expanded through addition of two dimensions including "*autonomy and competitive aggressiveness*" (Lumpkin and Dess 1996). Entrepreneurial orientation or posture as a strategic orientation reflects the collective actions and behaviors of an organization (Anderson and Covin 2014; Covin and Wales 2012; Knight 1997). An entrepreneurial firm prioritizes its innovative functions, undertaking risky actions, employing autonomy, engaging proactive actions, and compete aggressively towards its rivals in the market. In the literature, a complementary line of studies addressed the role entrepreneurial orientation on firm performance by asserting that firms that pursue entrepreneurial proclivity can achieve outstanding performance in their business environments (Boso et al. 2018; Kantur 2016; Lisboa et al. 2016). Although there is still a proliferating pattern in entrepreneurial orientation research, there are still ongoing discussions about its conceptualization. Despite this conflict, the most accepted and applied conceptualization of entrepreneurial orientation refers to "*the processes, practices, and decision-making activities that lead to new entry*" through being risk taker, innovative, autonomy, proactive, and taking aggressive actions (Wales 2016). An entrepreneurial organization is pervaded by these behavioral patterns at all levels within that organization

(Covin and Slevin 1991). Another organizational-level conceptualization of intrapreneurship is labeled as "*corporate entrepreneurship*" (Antoncic and Hisrich 2003; Guth and Ginsberg 1990; Hornsby et al. 1993; Ireland et al. 2009). Corporate entrepreneurship refers to "*the birth of new businesses within existing organizations and transformation of organizations through renewal of the new ideas on which they are built*" (Guth and Ginsberg 1990, p. 5). As a firm's strategy, corporate entrepreneurship echoes the strategic intention of continuous exploration and exploitation of opportunities in order to achieve sustainable growth (Kuratko and Audretsch 2013; Shane and Venkataraman 2000) by emphasizing the role of corporate venturing, and strategic renewal (Zahra 1991, 1993). While corporate venturing reflects creating of new businesses in an already existing organization, strategic renewal indicates the strategic change through entrepreneurial behaviors of organizational members (Blanka 2019; Guth and Ginsberg 1990). Although some studies use corporate entrepreneurship and entrepreneurial orientation interchangeably, the concept of corporate entrepreneurship is considered to encompass entrepreneurial orientation (Antoncic and Hisrich 2003; Ireland et al. 2009; Kuratko and Audretsch 2013; Wales 2016). Thus, entrepreneurial orientation is a part of corporate entrepreneurship manifested by organizations. In addition, Antoncic and Hisrich (2003) made an attempt to provide an integrative conceptualization of corporate entrepreneurship which is comprised of the eight dimensions including "*new ventures, new businesses, product/service innovativeness, process innovativeness, self-renewal, risk taking, proactiveness, and competitive aggressiveness*." All in all, the majority of the studies that address intrapreneurship at organizational level define intrapreneurship as "*entrepreneurship within existing organizations*" which reflects "*the internal entrepreneurial processes in existing firms and organizations*" (Antoncic and Hisrich 2003; Bager et al. 2010; Blanka 2019). In contrast to those who refer corporate entrepreneurship as intrapreneurship (Antoncic and Hisrich 2003), some scholars think that they are associated but different concepts (Åmo 2010).

According to some scholars, intrapreneurship indicates the role of entrepreneurial employees in an existing firm which reflects the construct's individual level nature (Guerrero and Peña-Legazkue 2013). As a bottom-up perspective of intrapreneurship, the entrepreneurial efforts of nonmanagerial or managerial employees are considered as the source of strategic renewal with their abilities to transform new ideas into valuable outcomes (Blanka 2019; Pinchot 1985). In this regard, the concept of intrapreneurship at individual level highlights the essence of employees with entrepreneurial behaviors and attitudes that contribute firm performance (Åmo and Kolvereid 2005; Guerrero and Peña-Legazkue 2013). The prominent characteristics of intrapreneurs that are pointed out by the majority of studies are proactiveness, innovativeness, creativity, ability to explore opportunities, risk taking, self-efficacy, and networking (Neessen et al. 2019).

Related Issues

The present volatile environment demands organizations to have the ability to cope with rapid changes through continuous innovation in order to achieve and maintain a competitive advantage. Accordingly, both individual and organizational level of intrapreneurship reflect the mechanisms necessary for not only for the organizational performance but also for economic and social development at national level. Therefore, firms are required to adopt an entrepreneurial posture to outperform their rivals in the marketplace and achieve a superior performance (Ireland et al. 2003; Kuratko and Audretsch 2013; Morris et al. 2011; Wales 2016; Zahra 1993). The role entrepreneurship has been scrutinized on innovation performance, firm performance in both domestic and international business context, firm capabilities including innovation, marketing and learning capabilities (Boso et al. 2018; Genc et al. 2019; Monteiro et al. 2019).

Regarding individual level perspective, the role of employees in firm capabilities to adopt to external environment is started to receive attention of the scholars. Intrapreneurship at individual

level is a part of these developments that address the contribution of employees with entrepreneurial characteristics to organizational level constructs (Gawke et al. 2019; Neessen et al. 2019). In conjunction with this perspective, the vital role of intrapreneurship was championed with the emphasis on the extent that entrepreneurial-thinking employees are the microlevel sources of firm competitive advantage and performance (Guerrero and Peña-Legazkue 2013). Intrapreneurial employees are able to cope with rapid changes and also ignite changes within an organization that can boost firms' strategic posture in the marketplace. In the pertinent literature, both the entrepreneurial characteristics of managerial and nonmanagerial employees have been tackled with their personalities, intentions, and factors that enable the appropriate climate for intrapreneurs to realize their ideas (Gawke et al. 2019; Neessen et al. 2019). For instance, intrapreneurs show proactive behaviors in their networks which provide them to be more open-minded and discover opportunities; thus, social embeddedness plays a crucial role for intrapreneurs. Furthermore, intrapreneurs need an environment with tolerance and support to enhance their entrepreneurial skills and utilize those skills. Especially, middle-level managers play a crucial role for aspiring entrepreneurial employees to exploit their skills and knowledge (Blanka 2019). In other words, an organizational culture and climate of trust with guiding and supportive managers and learning orientation enable intrapreneurs to foster their skills which in turn contribute firm level outcomes.

Summary

The role of entrepreneurship in countries' economic development is undeniable. As a subfield of entrepreneurship, intrapreneurship reflects the entrepreneurial spirit both in organizations and employees. As stated before, intrapreneurship as a multifacet construct is investigated at individual and organizational level of analysis. Besides, individual intrapreneurs that reside in an organization can conduce the promotion of

intrapreneurship at organizational level. Therefore, intrapreneurial employees can be the microlevel foundations of organizational level constructs. Intrapreneurial employees have sparked the crucial role human capital that contributes to organizational capabilities, resources, and firm performance and affect strategic direction of an organization. In this vein, firms need to provide necessary environment with appropriate organizational culture and climate that can foster intrapreneurial behaviors of employees, which in turn, can amplify the intrapreneurship at organizational level and the economic development level of a country. In terms of theoretical perspective, a holistic approach that integrates the dynamics between intrapreneurship at individual and organizational level with a bottom-up approach can be more insightful in order to comprehend the difference and association between the two levels of analysis of the construct, which can enable to clarify the conceptualization of the phenomenon.

Introduction

Conventional banking is based on the concept of interest which is widely acceptable in the western society. Conventional banks take full control of the ownership from the investors to manage their investments but forbid the investors to intervene in the management of their funds. The problem with the unchecked conventional banking system is compounded even further when it is able to loan money for mortgages at subprime rates, over evaluate it, and sell those loans as pseudo good investments to those who wish to purchase the debts as securities. The lack of regulations and integrity of conventional banks in the USA have left many westerners searching for a better option, especially after the collapse of the markets which led to the great depression in 1920s and the global recession in the 2007. As a result, awareness of the lack of overall integrity of conventional banks and the lending principles have grown over the past decade among citizens within western countries such as the USA, the UK, and emerging markets (McMillen and Issa 2010). It is also argued that greed and unfair distribution of resources by the conventional banks have been the underlying reasons for the failed markets in

the USA. Islamic banking may be an alternative to conventional banking as it has received a considerable attention worldwide and is found to be successful (Adebayo and Hassan 2013). In Islamic banking, the creation and charging of interest is considered an injustice and thus prohibited (Iqbal and Mirakhor 1987). To avoid interest, Islamic banks and their clients instead share a portion of the risk and profit in a joint venture. The aim of Islamic banking is to maximize social and economic returns to the whole society and to the concerned parties including stockholders and investors as depositors (Sabri 2008). Therefore, Islamic banking may be considered superior to conventional banking because its prudence in lending encourages financiers to invest directly in an entrepreneur's ventures (Venardos 2005). Further, Islamic banking is considered stable as it is not based on the credit expansion but on the benefits for both banks and consumers. As such, Islamic banks are more profitable, more responsive to downturn in economic conditions, and seen as more trustable than conventional banks. Islamic banking also provides good business opportunities as it adds diversity and innovation to an already mature financial sector. Therefore, it is not surprising that the UK is leading the race to become the world center of Islamic banking, as it has the most expert bankers, the most advanced regulations, and a government that remains committed to the sector's growth on both financial and social grounds. Islamic banking has also become the banking system of choice for both Muslims and non-Muslims who are concerned with ethical business practices, nonexploitation, and unfair labor practices, among others.

The purpose of this entry is to explain the principles of Islamic banking, the growth of the Islamic banking sector, the distinctions between the conventional and Islamic banking systems, and the challenges of the Islamic banking, followed by a conclusion.

Principles of Islamic Banking

Islamic ethical values consist of compassion, passion, and respect for others (Rahman 1976). One

of the propositions of Islamic banking is that individual welfare depends on the collective work and welfare of all individuals. Thus, people should care about other peoples' interests, and not just only about themselves. They cannot pursue only personal interests all the time (Al-Roubaie 2010). As a result, the ethical aspect of daily life is embedded in Islamic banking, lending and investing of money of shareholders (Li 2008). Interest is a wrong concept as it requires taking another person's wealth without consideration or reward. It destroys moral values; it breeds hatred and ill-will; it makes the rich grow richer while the poor poorer; and the creditor is disgraced (Rahman 1976). The basic principles of Islamic economic structure and financial system are based on the absenteeism of capitalist values and presence of communal non-individualistic values. Individual's lifestyle is influenced by one's religion – which has impact on consumption of goods and services. Over a period of time, the consumption process becomes associated with their religion (Choi et al. 2013) which is guided by religious beliefs and individual traits such as thrift, honesty, openness to complete strangers, and work ethic (Ferguson 2004). The financial downturn of 2007 and mortgage crises associated with it made customers. The option of implementing Islamic banking systems may also improve bank managers' accountability and thus achieve economic stability within the banking sector. Therefore the emergence of Islamic banks can be beneficial for the current financial markets. Indeed, one does not need to be a Muslim to use Islamic banking or Shari'ah-compliant financial products. These principles explain the growth in Islamic banking among both Muslim and non-Muslim communities worldwide.

The Growth of the Islamic Banking System

Islamic banks have over \$250 billion in assets (compared to \$6 billion in 1980s) and are expected to grow 10–15% annually (El-Hawary et al. 2007). In 2007, the United Arab Emirates alone issued over 50% of the global Islamic

bonds. The Arab financial sector is one of the most sophisticated and expanded sectors in the world economy as determined by the variety of institutions and financial products. This sector constitutes about 2% of the world, and about 12% of the emerging markets, making it an important player in the world of finances and banking sector (Sabri 2008). In the west, UK has become a major player in Islamic banking despite the hurdles that plague businesses operating in a non-Muslim financial environment. The potential global market of 1.5 billion Muslims – second largest religion in the world constituting 23% of the world's population – has drawn considerable attention to Islamic banking. Islamic banks operate in over 100 countries, out of which 20 are in Arab countries (Khan 2011). The largest Islamic Bank – the Faisal Islamic Bank (FIB) – enjoys a special status as a private Islamic institution which is guaranteed against nationalization and has tax and custom exemption status (Mallat 1998). The growth of the FIB and Islamic finance sector is attributed to several factors: increased demand for Shari'ah-compliant products from Islamic countries in emerging markets; the regulatory framework advancement relating to Islamic banking system; and increased demand from conventional investors for diversification. The banking operations and financing activities are based on Shari'ah principles that allow for fairer financial transactions, timely repayment of loans, and forgiveness of bad loans (Archer et al. 1998).

The Distinctions Between the Conventional and Islamic Banking Systems

The key feature that distinguishes Islamic banks from conventional banks is the repudiated use of interest financing. Islamic banking, based on the Shari'ah law, prohibits the payment or acceptance of interest charges. Rather than charging interests, Islamic banks typically share some of their borrowers' risks and profits. Under the law, the individual and the social good are regarded as complementary to each other rather than contradictory; a close relationship is fostered between

the two (Rahman 1976). Islamic banks primarily attract clients with religious beliefs and convince them through moral arguments for their business methods, much more than western banks do to engage their customers. In fact, Islamic banking is required to have superior relations with their clients. In the conventional banking system, lending on interest allows banks to sell money today with the intent of earning more money from interest in the future, regardless of the outcome of the loan. Risk falls predominantly on the loan taker while the bankers leverage against future earnings. It is unacceptable in Islamic banking. These distinctions may offer an insight as to how to stabilize the financial system of the west in the globalized world.

The Challenges of Islamic Banking

Islamic banking can be viewed as a risky option as it may be exposed to liquidity and operational and legal risks. Some argue that the growth in Islamic banking is due to revival of Islam and not necessarily due to the advantages of the Profit and Loss Sharing system based on Shari'ah law. A prospective Islamic banking institution may also need to deal with various local regulators such as Federal Reserve, State Banking Authorities, and Internal Revenue Service, among others. Although, for example, the US regulators have significant constitutional policies and economic reasons to accommodate the growth of Islamic banking, there is a limit to this accommodation in that the constitution prohibits the promotion of a particular religion over another by a public official or agency. Christians view Islamic banking as exploitive and unethical, and perceive it as a political, economic, and theological threat, and thus, paint Islam in a negative way. As a result, World Council of Churches and the Muslim Organization have opened dialogue at the national and international levels in an effort to develop an understanding based on the reciprocal willingness to listen and learn from each other. It is suggested that Islamic banking system needs greater standardization process and cooperation from institutions such as World Bank and IMF to regulate

operational framework and add more transparency and meaningfulness to their customers in order to be competitive with conventional banks and become service-oriented and responsive to innovation (Szczepanowicz 2011; Tahmina 2013).

Summary

Islamic banking is built on the fundamental principles of fairness and equity. It is forbidden to charge interest to customers. The bank managers can use the ethical principles of Islamic banking to their advantage in developing promotional strategies. For example, advertising campaigns can be more specific focusing on uniting people of different religions through Islamic banking. Currently, conventional and Islamic banks are seen as two rivals in the banking sector. Maintaining strong sustainability is vital to the existence of the both banking systems. However, the Muslim population being over 20% of the world's population, Islamic banks can contribute to significant economic stability. It can show to the skeptic people that Islamic banking, based on Shari'ah law, can contribute positively to solving modern finance needs. With its impressive estimated growth at US\$250 billion, western countries should look into the incentives to attract Islamic banks as foreign direct investments (FDI), particularly from emerging markets. Given the growth, Islamic banking has presence in several western countries. Since its initial growth in South Eastern Asian Countries in the 1990s, it has also seen a shift in growth toward the Gulf countries. The main reason for the shift came after the event of 9/11. In the past four decades, Islamic banking has successfully grown in number and size in countries such as Iran and Sudan, and has become popular in non-Muslim nations as well. The United Kingdom is leading in its efforts to remain a major player and committed to providing Islamic banking services to the growing population. More awareness and understanding of Islamic laws and laws from governing countries are needed to ensure the success of Islamic banking, as ethical standards need to be maintained at

all times. It can be demonstrated that Islamic financial products are Shari'ah compliant, that is, exhibit ethical and moral principles in addition to humanistic features designed to promote social justice, equity, and protect individual rights and freedom in the marketplace (Al-Roubaie 2010). The idea is that one does not need to be a Muslim to use Islamic banking services; anyone can use them. Indeed, Islamic banking sector can be used to bridge diverse cultures and yet co-exist in an economy with conventional banking and financial services.

Definition/Description

Islam is a comprehensive way of life. It offers a complete set of guidelines in various spheres of life be it material or spiritual. These guidelines are in the form of ethical principles such as honesty, sincerity, benevolence, adherence to social norms or paying due regard to societal interests. Islamic business ethics is a part of general ethical principles in the Islamic religion. These principles are derived from the revealed source in Islam that is the Quran. There are other sources of derived knowledge such as the sayings and actions of Prophet Mohammad. Islam shares many of its

ethical principles with the other two Abrahamic religions, Christianity and Judaism. There are significant diversions too. Business ethics in Islam is derived from the basic ethical principles of Islam that also have much in common with other world religions. Better known are the Islamic ethical principles of prohibition of usury or the forbidding of investment into undesirable businesses activities such as gambling. But there are a host of ethical principles in Islam that are relevant to the economy, trade and business. These include principles such as support to market economy, restricting the role of state in business, encouragement for healthy and fair competition, ethical selling, non-exploitative pricing or moderation in profit seeking.

Introduction

Ethics (also called moral philosophy) is a branch of philosophy that deals with the questions of what is right and wrong, moral and immoral or good and evil. It is a broad area of philosophy dealing with the study of which type of behavior is right and wrong. The rightness or wrongness of behavior is judged on the basis of moral standards. These standards are derived from multiple sources such as family, society, religion or philosophy. Business ethics (sometimes, also called corporate ethics) is a subset of ethics that deals with judging right or wrong behavior in the business setting.

Religion has a great impact on approaches to ethics that people adopt as it has widespread influence on how people lead their lives. This includes how people apply ethics to business dealings. It is generally accepted that economic sphere of life is also shaped by values derived from religion. Injunctions related to weights and measures, restrictions on investments into sinful activities, and directions for dealing with workers and employees are some of the examples of areas in which religious values impact businesses. All religions and denominations provide some guidelines to their adherents regarding the conduct of trade, commerce and business.

Islam, meaning submission, is one of the major religions of the world. It is an Abrahamic,

monotheistic religion believing in one God, Allah and Muhammad as the last prophet. It has nearly 2 billion followers called Muslims (those who submit to Allah) who make up one-fourth of the global population. Islam is a comprehensive way of life that provides to its followers, directions on various spheres of life including economic, material, philosophical, social, and spiritual. Among these spheres of life are the ethical principles to apply in the context of business.

Business Ethics

The term 'ethics' is derived from Greek *ethikos* that is itself derived from *ethos* which means custom, character or habit. It is a branch of philosophy - called moral philosophy - that deals with defining and developing the principles of right and wrong behavior. These principles are immutable such that they do not change and are not relative to situations or circumstances.

There are three categories of ethical theories: meta-ethics, normative ethics, and applied ethics. Meta-ethics deal with the nature of moral judgment whether it is absolute or derived. Normative ethics is concerned with the standards what defines rightness or wrongness. Applied ethics relates to morality and applications of concepts of ethics to various spheres of life and professions such as medical ethics or business ethics.

Business ethics deals with how personal moral norms apply to activities and goals of an organization. In doing so, business ethics tackles challenges posed by ethical dilemmas in the context of business. For example, a common issue is the primacy to be accorded to profitability versus social good that a business organization can do. Business ethics provides guidance to businesspeople on how they can deal with moral questions arising out of the day-to-day conduct of business activities. Business ethics is a system of values that helps to relate the goals and objectives of the organization and the techniques used to attain the goals to the ultimate ends. The ultimate ends are viewing needs and aspirations of individuals as a

part of society to which they belong and also to maintain their personal dignity.

Islamic Ethics

The understanding of Islamic ethics is derived from revealed as well as guided human-generated sources of knowledge derived from an active study of the *Quran*, *Ahadith*, *Sunnah*, *Fiqh* and *Tasawwuf*. *Quran* is the scripture revealed to the Prophet Muhammad by Allah, the Almighty and is the primary text of Islam. *Ahadith* (singular term is *Hadith*) are the statements of the Prophet and *Sunnah* the actions of the Prophet as narrated by his companions and passed on through a generation of authentic narrators. *Fiqh* is Islamic jurisprudence. *Tasawwuf* is the traditional Islamic science of self-improvement and spirituality. The sources of Islamic knowledge link ethics to faith and describe what is necessary for individuals as members of society and members of organizations.

There are three aspects that govern ethical conduct: character, intention, and the outcome. Character is built by virtues such as reason, knowledge, righteousness, and patience. Intention is the bedrock of ethical conduct and determines its rightness. Good intentions are necessary for achieving the right outcomes. The outcomes are to satisfy obligations to God, family and self. The concepts of *halaal* (desirable) and *haram* (forbidden) serve to distinguish between acts that are encouraged and forbidden as well as outcomes that are desirable and undesirable. Besides these, there are four other types of rules regarding the status of action. These are *mubah* (which is permissible), *wajib* (obligatory), *mandub* (recommended), and *makruh* (discouraged). Islam advocates a balance of outcomes in terms of satisfaction of different types of human needs such as physiological, economic or spiritual.

Islamic ethics is defined by Ali 2011 as “the specified rules that govern individuals and organizational conduct and seek to ensure generosity, transparency, and accountability in behavior and actions, while safeguarding societal interests.”

Beekun 1996 lists the axioms of Islamic ethical philosophy as: unity, equilibrium, free will, responsibility and benevolence. In Islam, ethics is viewed as the basis for achieving prosperity and well-being of individuals. It is also seen as necessary for achieving a sustainable economy and social goals. Reason is considered as the basis for distinguishing what is right and wrong and people may differ in their conduct based on their understanding. Three philosophical principles of *maslah aamah*, *wassatiyah*, and *ehsaan* guide the behavior in all spheres of life. *Maslah aamah* deals with the larger interest of people or society. *Wassatiyah* is moderation in all actions. *Ehsaan* is giving due regard to welfare of others and going beyond doing what is good. Ends do not justify the means in the Islamic perspective to ethics.

The evolution of human personality in Islam is seen in terms of different levels of existence that determine the conduct. The *Quran* describes these four levels of existence as: *sawala*, *ammara*, *lawama*, and *mutmainna*. *Sawala* is the stage of passion for temptation where self interest is predominant in human nature. *Ammara* is the prone to evil psyche, in which stage the person is aware that their soul pushes them to evil yet they put no resistance to that push. *Lawama* is stage where the person is aware of evil and the consequences of being evil. There is dilemma between good and evil indicating that the soul is striving towards good. *Mutmainna* is the stage that is the highest stage of human development. The person is away from evil and performs good deeds remaining satisfied and content. At each of these four stages the ethical implication is clear. Initially, a person is not concerned with ethics, and when aware he is still propelled towards evil. Later two stages indicate that ethical conduct is pursued and then attained.

Business Ethics in Islam

Business ethics in Islam, just like general ethics, derives its principles from the revealed and

guided human-generated sources of knowledge. It can be understood in the context of how ethics is defined. Islamic ethics, defined by Ali 2011, are “the specified rules that govern individuals and organizational conduct and seek to ensure generosity, transparency, and accountability in behavior and actions, while safeguarding societal interests” help to understand the concept and principles of business ethics in Islam. The ethical framework of public interest, moderation, and *ehsaan* determines the ethicality inherent in a given situation.

As an illustration, the concept of moderation in Islam applies to many business situations. Consumption, spending, saving, investment, risk taking and competition are common activities in which businesspeople are engaged. Overconsumption and conspicuous consumption is frowned upon in Islam. Spending is recommended in moderation. Neither miserliness nor extravagance is favored. Saving is encouraged so as to prevent harm from unforeseen risk and creating reserves for investing in future businesses. Investment is to be ensured in fair activities that are permissible. Investing in right avenues that yield good returns are preferable as they can be used for generosity and discharging social responsibilities. Risk taking is suggested in moderation so as to not harm the interests of the investors. Competition is encouraged provided it is fair, does not harm public interest, and is done observing *ehsaan* and moderation. Monopolies are not considered permissible as well as hoarding to affect prices unfairly. The role of the state in business is to be restricted to regulating business conduct to avoid abuse and fraud.

Ethics of profit in Islam has a broader reach and goes beyond the material concern of maximizing profitability and what is generally known as utilitarianism. Profitability is considered essential so long as it is fair and balanced, guided by spiritual concerns and faith, and keeps societal interests in view. Thus, Islam advocates profit moderation rather than profit maximization.

The ethics of selling requires the seller to not be exploitative. So long as moderate and fair

profit accrues from the transaction, it is permissible. Mutual goodwill is considered important for fair exchange of goods and services to take place. Transactions must be free of coercion and deception and take place in an environment of mutual trust and dependence. Pricing should be the outcome of the interplay of genuine supply and demand in the marketplace. The seller is enjoined to go beyond merely profit making and be kind and considerate to the needy and distressed by allowing them to buy on debt that may or may not be paid depending on circumstances.

There is a comprehensive set of ethical principles in Islam that can be applied to the area of management and human resource management. These include the application of the principles of public interest, moderation and *ehsaan* to management of day to day affairs in organizations. Employee-employer relationship in Islam is governed on the basis of fairness in dealings, adequate and timely compensation, and being considerate and kind in dealings. The employee is also expected to adhere to his commitment and serve his employer with loyalty and to the best of his ability.

There are certain taboos in Islamic ethics that are commonly known. These are charging of usury on financial transactions, indulging in business activities that are detrimental to individual and societal interest such as gambling, buying and selling of harmful drugs and alcohol, price manipulation, unfair dealings, weighing lesser than what is paid for, exhibiting greed and avarice in setting price and consumption, hoarding of goods to charge higher prices in times of distress, hoarding of wealth, counterfeiting among others. Avoidance of unethical actions is based on three factors as identified by Ali 2014. These factors are character, knowledge and spirituality. Character is the bedrock of good intentions and good actions. Knowledge is considered essential for discerning good from evil. Spirituality aids character and knowledge to be applied for the good of society.

Summary

Ethics is a branch of philosophy that deals with the questions of what is right and wrong. There are three categories of ethical theories: meta-ethics, normative ethics, and applied ethics. Business ethics is a subset of general ethics. It deals with how personal moral norms apply to activities and goals of an organization. Religion has a significant impact on how people lead their lives. It also influences the way how people manage the economy and commercial organizations.

The understanding of Islamic ethics is derived from revealed as well as guided human-generated sources of knowledge derived from an active study of the Quran, Ahadith, Sunnah, Fiqh and Tasawwuf. There are three aspects that govern ethical conduct: character, intention, and the outcome. The concepts of *halaal* (desirable) and *haram* (forbidden) serve to distinguish between acts that are encouraged and forbidden as well as outcomes that are desirable and undesirable.

Islamic ethics is defined by Ali (2011) as “the specified rules that govern individuals and organizational conduct and seek to ensure generosity, transparency, and accountability in behavior and actions, while safeguarding societal interests.” Business ethics in Islam is derived from the general ethical principles. Three philosophical principles of *maslah aamah*, *wassatiyah*, and *ehsaan* guide the behavior in all spheres of life. *Maslah aamah* deals with the larger interest of people or society. *Wassatiyah* is moderation in all actions. *Ehsaan* is giving due regard to welfare of others. The Quran describes these four levels of existence as: *sawala*, *ammara*, *lawama*, and *mutmainna* each level having implications for ethical actions.

The ethical framework of public interest, moderation, and *ehsaan* determines the ethicality inherent in a given situation. Ethics of profit in Islam has a broader reach and goes beyond the material concern of maximizing profitability. The ethics of selling requires the seller to not be exploitative and kind and considerate to those in distress. There are certain taboos in Islamic ethics that are commonly known such as avoidance of

usury and forbidding of trade and business in undesirable articles such as drugs and alcohol. A combination of character, knowledge and spirituality can serve to deal with unethical conduct and behavior.

Definition

Islamic finance is a financial system consistent with the ethics and values of Islam (Bashir 1999) that affect Islamic economics and the overall Islamic social system.

Five pillars constitute the basic norms of Islamic practice: the declaration of faith (*shahada*), prayer (*salah*), alms-giving (*zakat*), fasting (*sawm*), and pilgrimage (*hajj*). The ethical and moral tenets of the Islamic faith are accepted by Muslims – the world’s second-largest religious group that, in turn, includes several branches and doctrinal tendencies. The largest branches are Shia (*Shī‘as*) and Sunni (*Sunnīs*), while others are relatively small in size (*Ibadis*, *Zaydīs*, *Ismā‘īlīs*). Within Islamic groups, there may be differences in terms of orders (*tariqa*) within Sufism and Sunni Islam and schools of theology (*Aḥharī*, *Ash‘arī*, *Māturīdī*) and jurisprudence (*Ḥanafī*, *Mālikī*, *Shāfi‘ī*, *Ḥanbalī*).

Maulana Maududi (1903–1979) is considered the father of the idea of an Islamic economy and Islamic finance (Maududi 1999; Slomp 2007) that allows practitioners and customers to comply with God’s commandments, revealed in the *Sharia*. Indeed, Islamic financial relations are based on Islamic religious law, referred to as *Sharia’a* law. Islamic finance claims to follow the precepts that rule all aspects of a Muslim’s life. Such a foundation makes a substantial difference compared to Western finance and provides a viable alternative to conventional finance.

The Holy Koran (*Qur’an*) is the primary source of *Sharia’a* law. In addition, Islamic finance has been influenced by the Sunnah of the Prophet Mohammad, the *Ijma* (consensus opinions of learned men and jurist), and the *Qiyas* (analogies to existing laws).

These sources lead to many restrictions and complexities in the Islamic financial relationship based on the following pillars:

1. The payment of interest is proscribed: since money cannot make money, *riba* (the Western current forms of interest) is strictly prohibited as argued by the leading specialists in Islamic jurisprudence (*fuqaha* or *fiqh scholars*) (Visser 2009; Ahmad 2011).
2. Speculation is proscribed: speculative behavior is considered gambling (*maysir*). Gaming activity is clearly forbidden by both the injunction against “making money out of money” and the moral code embedded in *Sharia’a* law (Shaffai 2008). Speculation is also considered as creating prohibited uncertainty/risk (*gharar*). The latter takes on two forms: (1) uncertainty refers to asymmetric information among contracting parties where one set of agents has relatively superior information and (2) it relates to immeasurable risk and the lack of any reliable information with which to base business judgments. Accordingly, avoiding either situation leads to financial relations that are less risky than would occur in conventional banking relations. Namely, the prohibition of *gharar*, carrying the connotation of deception and illusion, is the essence of Islamic contract law.
3. In financial transactions, the bearing risk is proscribed. It is unacceptable to pay money in return for a reduction in uncertainty or risk. As a result, conventional insurance cannot be authorized and future contracts are considered inconsistent with the *Sharia*. The principles and the subsequent prohibitions against interest and speculation lead to lending relations that must be assessed (Chirinko et al. 2018).

Moreover, Muslims must avoid forbidden products and services, *haram*. The list includes

alcoholic drinks, pork-related products, adult entertainment, and gambling. Another important peculiarity is that there can only be one transaction per contract; for example, a sales transaction and a lease agreement must be two separate contracts. Furthermore, Muslim creditors are obliged to show clemency toward debtors who cannot make repayments (Visser 2012).

Introduction

The evolution and spread of Islamic financial institutions in the last two decades have generated a growing interest over time and triggered a worldwide discussion among policymakers, practitioners, and economists (Bashir 1999). In the United States the resurgence of their interest (Sivan 1990) dates back to the 1960s and the 1970s, after the earliest experimental Islamic banks instituted interest-free savings and loans for societies in Pakistan and the Indian subcontinent; then they established pioneering ventures in the 1960s in Egypt and Malaysia. Islamic finance became a trillion-dollar industry after enjoying sudden success in the private sector in Gulf states such as Dubai in the 1970s. By 1985 more than 50 conventional banks worldwide offered Islamic financial products, which progressively spread throughout Saudi Arabia, the Middle East, South and Southeast Asia, Africa, Europe, and the Americas, as investor interest in Islamic finance products continued growing.

The products, services, and contracts that *Sharia*-compliant finance offers differ from conventional banking and can be categorized into three broad groups (Table 1). Some of them encompass *Wadiah* (safe-keeping), *Mudharabah* (profit sharing), *Murabahah* (cost plus finance), *Musharakah* (joint venture), *Ijar* (leasing), *Hawala* (an international fund transfer system), *Takaful* (Islamic insurance), and *Sukuk* (Islamic bonds) (Jamaldeen 2012; Khan 2015; Rizvi et al. 2016).

It has been said that conventional banking and Islamic banking have the same purpose or basic goal, but the latter conforms to the rules of *Sharia* law; accordingly, several activities are forbidden:

Islamic Finance, Table 1 Islamic banking products

Profit and loss sharing modes (<i>musharakah</i> and <i>mudharabah</i>)	Profits and losses are grounded on partnership contracts
Asset-backed financing (trade-based financing or non-people-location-service financing)	These tools comprise mark-up (<i>murabahah</i>), leasing (<i>ijar</i>), cash advances adopted in the agricultural (<i>salam</i>) or manufacturing sectors (<i>istisna</i>) Among the typical debt financing tools in Islamic banking, <i>bai-bithaman ajil</i> and <i>murabahah</i> are mostly being used in the Malaysian banking sector
Modes based on safety and security contracts and agency contracts (<i>wakalah</i>).	They comprise safe-keeping contracts (<i>wadiah</i>) for current account deposits and agency contracts (<i>wakalah</i>)

- Charging or paying interest (*riba*); transactions (*Fiqh al-Muamalat*) that have been designed to impede charging interest
- Investing in organizations connected to prohibited activities (*haram*), that is, vending alcohol or producing media such as pornography
- Expecting additional revenues for late payments
- *Maisir*, typically conceived as gambling but more customarily extended to speculation (i.e., derivatives or futures)
- *Gharar*, considered uncertainty or ambiguity, to steer clear of excessive risk and fraudulent behavior that can support derivative tools
- Involvement in transactions devoid of material finality since all transactions must be directly connected to a real underlying economic transaction, thus omitting options and most other derivatives

Each Islamic bank transaction is supervised and advised by a board of *shariah* experts to guarantee that all activities are consistent with Islamic principles.

The body of research in Islamic banking and finance includes both descriptive studies

addressing conceptual issues underlining interest-free financing (Ahmed 1981; Karsen 1982) and neoclassical techniques adopted to analyze the theoretical framework of Islamic institutions (Khan 1986; Haque and Mirakhor 1986). Islamic finance has been conceived as an especially momentous phenomenon (Visser 2009).
